## Predicting the Power Dissipation of Actel FPGAs

## Introduction

Calculating the power dissipation of field programmable gate arrays (FPGAs) is similar to using the calculations for other CMOS ASIC devices, such as gate arrays and standard cells. The power dissipation depends on such factors as utilization, average operating frequency, and load conditions. In contrast, most PALs and PLDs have a fixed power consumption.
This application note discusses power dissipation and the concept of equivalent power capacitance. The general approach to calculating power in an Actel device will be described using equivalent power capacitance values for the devices. This general equation is useful if internal switching frequencies can be accurately determined. Since this is often difficult to do, a set of approximation curves based on average frequency rules of thumb are provided. The graphs provide an upper limit estimate for active power sufficient for most designs.

## General Power Equation

$$
\begin{gather*}
P=\left[I_{\mathrm{CC}} \operatorname{standby}+I_{\mathrm{CC}} \text { active }\right] * V_{\mathrm{CC}}+I_{\mathrm{OL}} * \mathrm{~V}_{\mathrm{OL}} * N+ \\
I_{\mathrm{OH}} *\left(\mathrm{~V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{OH}}\right) * \mathrm{M} \tag{1}
\end{gather*}
$$

Where:
$I_{\text {CCstandby }}$ is the current flowing when no inputs or outputs are changing.
$I_{C C}$ active is the current flowing due to CMOS switching.
$\mathrm{I}_{\mathrm{OL}}$ and $\mathrm{I}_{\mathrm{OH}}$ are TTL sink/source currents.
$\mathrm{V}_{\mathrm{OL}}$ and $\mathrm{V}_{\text {OH }}$ are TTL level output voltages.
$N$ equals the number of outputs driving TTL loads to $\mathrm{V}_{\mathrm{OL}}$.
$M$ equals the number of outputs driving TTL loads to $\mathrm{V}_{\mathrm{OH}}$.
Determining N and M depends on the design and the system I/O. An accurate determination of power dissipation comes from two components, static and active, which are considered separately.

## Static Power Component

Actel FPGAs have small static power components that result in lower power dissipation than PALs or PLDs. By integrating multiple PALs/PLDs into one FPGA, an even greater reduction in board-level power dissipation can be achieved.

The power due to standby current is typically a small component of the overall power. For an ACT 3 device, the standby power is specified as 5 mWatts , worst case.
The static power dissipated by TTL loads depends on the number of outputs driving high or low and the DC load current. Again, this value is typically small. For instance, a 32-bit bus sinking 4 mA at 0.33 V will generate 42 mWatts with all outputs driving low and 140 mWatts with all outputs driving high. The actual dissipation will average somewhere between as I/Os switch states with time.

## Active Power Component

Power dissipation in CMOS devices is usually dominated by the active (dynamic) power dissipation. This component is frequency dependent, a function of the logic and the external I/O. Active power dissipation results from charging internal chip capacitances of the interconnect, unprogrammed antifuses, module inputs, and module outputs, plus external capacitance to PC board traces and load device inputs. An additional component of the active power dissipation is the totem-pole current in CMOS transistor pairs. The net effect can be associated with an equivalent capacitance that can be combined with frequency and voltage to represent active power dissipation.

## Equivalent Capacitance

The power dissipated by a CMOS circuit can be expressed by the equation:

$$
\begin{equation*}
\text { Power ( } \mu \text { Watts })=\mathrm{C}_{\mathrm{EQ}} * \mathrm{~V}_{\mathrm{CC}}{ }^{2} * \mathrm{~F} \tag{2}
\end{equation*}
$$

Where:
$C_{E Q}$ is the equival ent capacitance expressed in pF .
$V_{C C}$ is the power supply in volts.
F is the switching frequency in MHz .
Equivalent capacitance is calculated by measuring I ccactive at a specified frequency and voltage for each circuit component of interest. Measurements have been made over a range of frequencies at a fixed value of $\mathrm{V}_{\mathrm{CC}}$. Equivalent capacitance is frequency independent so that the results may be used over a wide range of operating conditions. The results for ACT 1, ACT 2, 1200XL, and ACT 3 devices are given in Table 1.

Table 1-CEQ Values for Actel FPGAs

|  | ACT 1 | ACT 2 | 1200XL | ACT 3 |
| :--- | ---: | :---: | :---: | :---: |
| Modules | 6.3 | 7.7 | 7.7 | 8.2 |
| Input Buffers | 16.0 | 18.0 | 18.0 | 1.5 |
| Output Buffers | 25.0 | 25.0 | 25.0 | 2.3 |
| Clock Buffer Loads | 5.3 | 2.5 | 2.5 | $\mathrm{~N} / \mathrm{A}$ |
| I/O Clock Buffer Loads | $\mathrm{N} / \mathrm{A}$ | $\mathrm{N} / \mathrm{A}$ | $\mathrm{N} / \mathrm{A}$ | 0.4 |
| Dedicated Array Clock | $\mathrm{N} / \mathrm{A}$ | $\mathrm{N} / \mathrm{A}$ | $\mathrm{N} / \mathrm{A}$ | 0.5 |
| Buffer Loads | $\mathrm{N} / \mathrm{A}$ | $\mathrm{N} / \mathrm{A}$ | $\mathrm{N} / \mathrm{A}$ | $0.5+$ <br> fixed/ <br> Routed Array Clock |
| Buffer Loads |  |  |  | device |

Finding the active power dissipated from the complete design requires solving Equation 2 for each component type. This requires the switching frequency of each part of the logic. The exact equation is a piecewise linear summation over all components as shown in Equation 3. For ACT 1, ACT 2, and 1200XL devices:

$$
\begin{gather*}
\text { Power }=\left[\left(m * C_{E Q} * f_{m}\right)_{\text {modules }}+\left(n * C_{E Q} * f_{n}\right)_{\text {Inputs }}+\right. \\
\left.\left(p *\left(C_{E Q}+C_{L}\right) * f_{p}\right)_{\text {Outputs }}+\left(q^{*} C_{E Q} * f_{q}\right)_{\text {clk_loads }}\right] \\
* V_{C C} \tag{3}
\end{gather*}
$$

Where:
$m=$ Number of logic modules switching at frequency $f_{m}$
$n=$ Number of input buffers switching at frequency $f_{n}$
$p=$ Number of output buffers switching at frequency $f_{p}$
$\mathrm{q}=$ Number of clock loads on the global clock network
$\mathrm{f}_{\mathrm{m}}=$ Average logic module switching rate in MHz
$\mathrm{f}_{\mathrm{n}}=$ Average input buffer switching rate in MHz
$\mathrm{f}_{\mathrm{p}}=$ Average output buffer switching rate in MHz
$\mathrm{f}_{\mathrm{q}}=$ Frequency of global clock
$C_{L}=$ Output load capacitance
For ACT 3 devices:

$$
\begin{gather*}
\text { Power }(\mu W)=\left[\left(m \times 8.2 \times f_{1}\right)+\left(n \times 1.5 \times f_{2}\right)+\right. \\
\left(p \times\left(2.3+C_{L}\right) \times f_{3}\right)+\left(q \times 0.5 \times f_{4}\right)+\left(\left(r_{1}+0.5 r_{2}\right) \times f_{5}\right)+ \\
\left.\left(s \times 0.4 \times f_{6}\right)\right] \times V_{C C}^{2} \tag{4}
\end{gather*}
$$

Where:
$m=$ Number of logic modules switching at $f_{1}$
$n=$ Number of input buffers switching at $f_{2}$
$p=$ Number of output buffers switching at $f_{3}$
$\mathrm{q}=$ Number of clock loads on the dedicated array clock network

| A1415: |  |
| :--- | :--- |
| A1425: |  |
| A1440: |  |
| A $=104$ |  |
| A1460: |  |
| A14100: |  |
| A $=288$ |  |
|  | $q=697$ |

$r_{1}=$ Fixed capacitance due to routed array clock network

| A1415: | $r_{1}=60$ |
| :--- | :--- |
| A1425: | $r_{1}=75$ |
| A1440: | $r_{1}=105$ |
| A1460: | $r_{1}=145$ |
| A14100: | $r_{1}=195$ |

$r_{2}=$ Number of clock loads on the routed array clock network
s = Number of clock loads on the dedicated I/O clock network

| A1415: | $s=80$ |
| :---: | :---: |
| A1425: | $s=100$ |
| A1440: | $s=140$ |
| A1460: | $\mathrm{s}=168$ |
| A14100: | $\mathrm{s}=228$ |

$\mathrm{f}_{1}=$ Average logic module switching rate in MHz
$\mathrm{f}_{2}=$ Average input buffer switching rate in MHz
$\mathrm{f}_{3}=$ Average output buffer switching rate in MHz
$\mathrm{f}_{4}=$ Average dedicated array clock rate in MHz
$\mathrm{f}_{5}=$ Average routed array clock rate in MHz
$\mathrm{f}_{6}=$ Average dedicated $\mathrm{I} / \mathrm{O}$ clock rate in MHz
$C_{L}=$ Output load capacitance in pF
Since all of the modules or inputs or outputs do not switch at the same frequency, a weighted average can be used. For example, a design consisting of 100 modules switching at 10 MHz and 200 modules switching at 5 MHz would have a weighted average frequency of:

$$
f_{\text {ave }}=[(100 * 10)+(200 * 5)] /(100+200)=6.67 \mathrm{MHz}
$$

## Determining Average Frequency

Determining the exact average frequency for a design requires a detailed understanding of the data input values to the circuit. Logic simulation can provide insight into average frequency, although simulation is limited by the percentage of real-time stimulus that can be applied. Fortunately, studies based on large numbers of ASIC designs have been made to determine rules of thumb for average switching frequency in logic circuits. These rules are meant to represent worst-case scenarios, hence their use for predicting the upper limits of power dissipation is generally acceptable. The rules given in Tables 2 and 3 are for ACT 1, ACT 2, and 1200XL devices. Table 4 gives the rules for ACT 3 devices. Using these rules, we can develop power estimates.

Table 2 - Rules for Determining Average Frequency for ACT 1 Family

$$
\begin{array}{|ll}
\hline \text { 1. } & \text { Module Utilization }=90 \% \\
\text { 2. } & \text { Average Module Frequency }=F / 10 \\
\text { 3. } & 1 / 3 \text { of } I / \text { Os are Inputs } \\
\text { 4. } & \text { Average Input Frequency }=F / 5 \\
5 . & 2 / 3 \text { of } I / \text { Os are Outputs } \\
6 . & \text { Average Output Frequency }=F / 10 \\
\text { 7. } & \text { Clock Net Loading }=45 \% \\
8 . & \text { Clock Net Frequency }=F \\
\hline
\end{array}
$$

Table 3 - Rules for Determining Average Frequency for ACT 2 and 1200XL Families

| 1. | Module Utilization $=80 \%$ of combinatorial modules |
| :--- | :--- |
| 2. | Average Module Frequency $=\mathrm{F} / 10$ |
| 3. | $1 / 3$ of $\mathrm{I} /$ Os are Inputs |
| 4. | Average Input Frequency $=\mathrm{F} / 5$ |
| 5. | $2 / 3$ of $\mathrm{I} /$ Os are Outputs |
| 6. | Average Output Frequency $=\mathrm{F} / 10$ |
| 7. | Clock Net 1 Loading $=40 \%$ of sequential modules |
| 8. | Clock Net 1 Frequency $=\mathrm{F}$ |
| 9. | Clock Net 2 Loading $=40 \%$ of sequential modules |
| 10. | Clock Net 2 Frequency $=\mathrm{F} / 2$ |

Table 4 - Rules for Determining Average Frequency for ACT 3 Family

|  | Logic Modules (m) | $\begin{aligned} & =80 \% \text { of } \\ & \text { modules } \end{aligned}$ |
| :---: | :---: | :---: |
|  | Average module switching rate $\left(\mathrm{f}_{1}\right)$ | $=F / 10$ |
| 3. | Inputs switching ( n ) | = \# I/Os used/12 |
|  | Average input switching rate ( $\mathrm{f}_{2}$ ) | $=\mathrm{F}$ |
|  | Outputs switching (p) | = \# I/Os used/15 |
|  | Output loading ( $\mathrm{C}_{\mathrm{L}}$ ) | $=35$ |
|  | Average output switching rate ( $\mathrm{f}_{3}$ ) | $=F / 2$ |
|  | Dedicated array clock loads (q) | = fixed by device |
|  | Average dedicated array switching rate $\left(\mathrm{f}_{4}\right)$ | $=\mathrm{F}$ |
|  | Routed array fixed capacitance $\left(r_{1}\right)$ | = fixed by device |
|  | Routed array clock loads ( $\mathrm{r}_{2}$ ) | $\begin{aligned} = & 40 \% \text { of } \\ & \text { sequential } \\ & \text { modules } \end{aligned}$ |
|  | Average routed array switching rate ( $\mathrm{f}_{5}$ ) | $=\mathrm{F} / 2$ |
|  | I/O clock loads (s) | = \# I/Os used |
|  | Average $\mathrm{I} / \mathrm{O}$ switching rate ( $\mathrm{f}_{6}$ ) | $=\mathrm{F}$ |

## Average Frequency Example

While some portions of a logic design switch at the system frequency, F, most of the logic switches at a reduced (or divided) frequency. Consider a 16 -bit synchronous counter with a system input clock equal to F as shown in Figure 1.

Figure 1 • 16-Bit Synchronous Counter

Where:
The Q0 output is switching at $\mathrm{F} / 2\left(\right.$ or $\left.1 / 2^{1}\right)$,
The Q1 output is switching at $\mathrm{F} / 4\left(\right.$ or $\left.1 / 2^{2}\right)$,
The Q15 output is switching at $\mathrm{F} / 65536$ (or $1 / 2^{16}$ ).
The average frequency is:
$F_{\text {ave }}=1 / 16^{*}\left(1 / 2^{1}+1 / 2^{2}+\ldots \ldots \ldots 1 / 2^{16}\right) \cong F / 16$
Thus, the average frequency of an $n$-bit synchronous counter switching at FHz is $\mathrm{F} / \mathrm{n}$.

Estimated Power
The rules in Tables 2 and 3 are applied to ACT 1, ACT 2, and 1200XL devices. The resulting power components are detailed in Tables 5 and 6 , and the total device power is shown in Figures 2 and 3. The graphs provide a simple guideline for estimating power. The tables may be interpolated when your application has different resource utilizations or frequencies. Table 4 details the rules applied to ACT 3 devices.
