II. TOTAL IONIZING DOSE (TID) TESTING

This testing is designed on the base of an extensive database (see, for example, TID data of antifuse-based FPGA in <http://www.klbs.org/> and <http://www.actel.com/>) accumulated from the TID testing of many generations of antifuse-based FPGAs. One distinctive quality about this testing is the bench measurement of electrical parameters. Compared to an automatic-tester measurement, the bench measurement provides lower noise, better accuracy and flexibility. The bench measurement samples pins for the measurements. However, two factors make sampling appropriate: first, the tolerance is often determined by either the I_{CC} or propagation delay, both are global parameters; second, the total dose effect is uniformly distributed across the chip.

A. Device-Under-Test (DUT) and Irradiation Parameters

Table 1 lists the DUT and irradiation parameters. During irradiation each input and most of the output is grounded through a 100k-ohm resistor; during annealing each input or output is tied to the ground or V_{CCI} with a 2.7-k ohm resistor. Appendix A contains the schematics of the irradiation-bias circuit.

B. Test Method

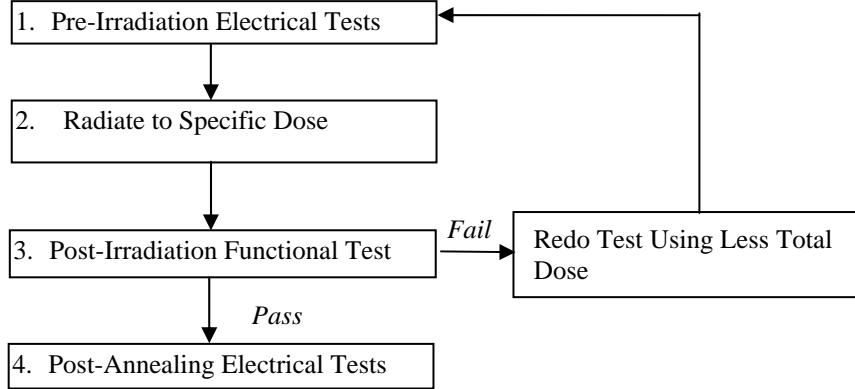

Figure 1 Parametric test flow chart

The test method generally follows the guidelines in the military standard TM1019. Figure 1 is the flow chart showing the steps for parametric tests, irradiation, and post-irradiation annealing.

The accelerated aging, or rebound test mentioned in TM1019 is unnecessary because there is no adverse time dependent effect (TDE) in products manufactured by sub-micron CMOS technology. Elevated temperature annealing reduces the effects originated from radiation-induced leakages. As indicated by testing data in the following sections, the predominant radiation effects in RTAX250S are due to radiation-induced leakages.

Room temperature annealing is performed in this test; the duration is approximately 10 days.

C. Design and Parametric Measurements

DUTs use a high utilization generic design (RTAX250S_TID) to test total dose effects in typical space applications. Appendix B contains the schematics and Verilog files for the logic design.

Table 2 lists each electrical parameter to be measured and the corresponding logic design. The functionality is measured on the output pin (O_{BS}) of a combinational buffer-string with 2,300 buffers, output pins (O_{ANDP_CLKF} , O_{ORP_CLKF} , O_{FF_CLKF} , O_{ANDC_CLKF} , O_{ORC_CLKF} , O_{ANDP_CLKG} , O_{ORP_CLKG} , O_{FF_CLKG} , O_{ANDC_CLKG} , O_{ORC_CLKG} , O_{ANDP_CLKH} , O_{ORP_CLKH} , O_{FF_CLKH} , O_{ANDC_CLKH} , O_{ORC_CLKH} , O_{ANDP_HCLKA} , O_{ORP_HCLKA} , O_{FF_HCLKA} , O_{ANDC_HCLKA} , and O_{ORC_HCLKA}) of four (4) shift registers with 1,312 bits total, and half of the output pins ($OUTX0$, $OUTX1$, $OUTX2$, $OUTX3$, $OUTX4$, $OUTX5$, $OUTX6$ and $OUTX7$) of the embedded RAM configured as 2048x6.

I_{CC} is measured on the power supply of the logic-array (I_{CCA}) and I/O (I_{CCI}) respectively. The input logic threshold (V_{IL}/V_{IH}) is measured on single-ended inputs EN8, DA, IO_I1, IO_I2, IO_I3, IO_I4, IO_I5 and IO_I6, and also on differential inputs DIO_I1P, DIO_I2P, DIO_I3P, DIO_I4P, DIO_I5P, DIO_I6P and DIO_I7P. The differential inputs are configured as LVPECL instead of LVDS. Because LVPECL uses 3.3 VDC, higher than 2.5 VDC used by LVDS, it is the worst case among the differential pairs. During the measurement on the differential inputs, the N (negative) side of the differential pair is biased at 1.8 V. The output-drive voltage (V_{OL}/V_{OH}) is measured on QA0. The propagation delay is measured on the output (O_{BS}) of the buffer string. The definition is the time delay from the triggering edge at the CLOCK input to the switching edge at the output O_{BS} . Both the delays of low-to-high and high-to-low output transitions are measured; the reported delay is the average of these two measurements. The transition characteristics, measured on the output O_{BS} , are shown as oscilloscope snapshots.

III. TEST RESULTS

A. Functionality

Every DUT passed the pre-irradiation and post-annealing functional tests. The as-irradiated DUT is functionally tested on the output (O_FF_HCLKA) of the largest shift register.

B. Power Supply Current (I_{CCA} and I_{CCI})

Table 3 summarizes the pre-irradiation, post-irradiation and post-annealing I_{CC} . The post-annealing I_{CC} for four different bit patterns, all '0', all '1', checkerboard and inverted-checkerboard, in the RAM are basically the same value.

F. Propagation Delay

Table 8 lists the pre-irradiation and post-annealing propagation delays. The results show small radiation effects; the negative degradations are probably due to measurement noise.
