1 Revision History

The revision history describes the changes that were implemented in the document. The changes are listed by revision, starting with the most current publication.

1.1 Revision 1.1

Revision 1.1 was published in June 2018. The following is a summary of changes.

- Figure 3 was removed.
- Retention characteristics were specified in the section Non-Volatile Characteristics (see page 45).

1.2 Revision 1.0

Revision 1.0 was published in March 2018. It was the first publication of this document.

2 Overview

This datasheet describes PolarFire® XT FPGA device characteristics with industrial temperature range (–40 °C to 100 °C T_J) and extended commercial temperature range (0 °C to 100 °C T_J). The devices are provided with a standard speed grade (STD) and a –1 speed grade with higher performance. The FPGA core supply V_{DD} can operate at 1.0 V for lower-power or 1.05 V for higher performance. Similarly, the transceiver core supply V_{DDA} can also operate at 1.0 V or 1.05 V. Users select the core operating voltage while creating the project.

6.2.2 Maximum Allowed Overshoot and Undershoot

During transitions, input signals may overshoot and undershoot the voltage shown in the following table. Input currents must be limited to less than 100 mA per latch-up specifications.

The maximum overshoot duration is specified as a high-time percentage over the lifetime of the device. A DC signal is equivalent to 100% of the duty-cycle.

The following table shows the maximum AC input voltage (V_{IN}) overshoot duration for HSIO.

Note: For proper operation of programming recovery mode, if a VDD supply brownout occurs during programming, a minimum supply ramp down time for only the VDD supply is recommended to be 10 ms or longer by using programmable regulator or on-board capacitors.

6.2.2.2 Hot Socketing

The following table lists the hot-socketing DC characteristics over recommended operating conditions.

Table 11 • Hot Socketing DC Characteristics over Recommended Operating Conditions

Parameter	Symbol	Min	Typ	Max	Unit	Condition
Current per transceiver Rx input pin (P or N single-ended)[1, 2]	I_{XCVRRX_HS}			±4	mA	V_{DDA} = 0 V
Current per transceiver Tx output pin (P or N single-ended)[3]	I_{XCVRTX_HS}			±10	mA	V_{DDA} = 0 V
Current per transceiver reference clock input pin (P or N single-ended)[4]	$I_{XCVRREF\_HS}$			±1	mA	$V_{DD\_XCVR\_CLK}$ = 0 V
Current per GPIO pin (P or N single-ended)[5]	I_{GPIO_HS}			±1	mA	V_{DDIx} = 0 V
Current per HSIO pin (P or N single-ended)						Hot socketing not supported in HSIO.

1. Assumes that the device is powered-down, all supplies are grounded, AC-coupled interface, and input pin pairs are driven by a CML driver at the maximum amplitude (1 V pk–pk) that is toggling at any rate with PRBS 2^7 data.
2. Each P and N transceiver input has less than the specified maximum input current.
3. Each P and N transceiver output is connected to a 40 Ω resistor (50 Ω CML termination – 20% tolerance) to the maximum allowed output voltage (V_{DDAmax} + 0.3 V = 1.4 V) through an AC-coupling capacitor with all PolarFire device supplies grounded. This shows the current for a worst-case DC coupled interface. As an AC-coupled interface, the output signal will settle at ground and no hot socket current will be seen.
4. $V_{DD\_XCVR\_CLK}$ is powered down and the device is driven to $–0.3\ V < V_{IN} < V_{DD\_XCVR\_CLK}$.
5. V_{DDIx} is powered down and the device is driven to $–0.3\ V < V_{IN} <$ GPIO V_{DDImax}.

Note: The following dedicated pins do not support hot socketing: TMS, TDI, TRSTB, DEVRST_N, and FF_EXIT_N. Weak pull up (as specified in GPIO) is always enabled.

6.3 Input and Output

The following section describes:

1. Measured across P to N with 400 mV bias.
2. Thevenin impedance is calculated based on independent P and N as measured at 50% of V_{DDI}.
3. For 50 Ω/75 Ω/150 Ω cases, nearest supported values of 40 Ω/60 Ω/120 Ω are used.
4. Measured at 50% of V_{DDI}.
5. Supported terminations vary with the IO type regardless of V_{DDI} nominal voltage. Refer to Libero for available combinations.

1. Measurements are made at typical, minimum, and maximum V_{REF} values. Reported delays reflect worst-case of these measurements. V_{REF} values listed are typical. Input waveform switches between V_L and V_H. All rise and fall times must be 1 V/ns.
2. Differential receiver standards all use 250 mV V_{ID} for timing. V_{CM} is different between different standards.
3. Input voltage level from which measurement starts.
4. The value given is the differential input voltage.
5. This is an input voltage reference that bears no relation to the V_{REF}/V_{MEAS} parameters found in IBIS models or shown in Output Delay Measurement—Single-Ended Test Setup (see page 26).
6. Emulated bi-directional interface.

7.6.4 Digest Cycles

Digests verify the integrity of the programmed non-volatile data. Digests are a cryptographic hash of various data areas. Any digest that reports back an error raises the digest tamper flag.

–40 to 55	–40 to 55	20 × LF	20 × LF	20 × LF	20 × LF	20 × LF	20 × LF	20 × LF	°C	Years

1. LF = Lifetime factor as defined by the number of programming cycles the device has seen under the conditions listed in the following table.

Table 65 • FPGA Programming Cycles Lifetime Factor

Programming T_J	Programming Cycles	LF
–40 °C to 100 °C	500	1
–40 °C to 85 °C	1000	0.8
–40 °C to 55 °C	2000	0.6

Notes:
The maximum number of device digest cycles is 100K.
Digests are operational only over the –40 °C to 100 °C temperature range.
After a program cycle, an additional N digests cycles are allowed with the resultant retention characteristics for the total operating and storage temperature shown.
Retention is specified for total device storage and operating temperature.
All temperatures are junction temperatures (T_J).

Example 1: 500 digests cycles are performed between programming cycles. N = 500. The operating conditions are –40 °C to 85 °C T_J. 501 programming cycles have occurred. The retention under these operating conditions is 20 × LF = 20 × .8 = 16 years.

Example 2: One programming cycle has occurred, N = 1500 digest cycles are occurred. Temperature range is –40 °C to 100 °C. The resultant retention is 10 × LF or 10 years over the industrial temperature range.

Parameter	Devices	Typ	Max	Unit
Standalone verification over JTAG	MPF300XT		90	s
Standalone verification over SPI-Slave	MPF300XT		55	s

Notes:
Standalone verify is limited to 2000 total device hours over the industrial –40 °C to 100 °C temperature. Use the digest system service, for verify device time more than 2000 hours.
Standalone verify checks the programming margin on both the P and N gates of the push-pull cell. Digest checks only the P side of the push-pull gate. However, the push-pull gates work in tandem. Digest check is recommended if users believe they will exceed the 2000 hour verify time specification.
Verification over JTAG: Programmer: FlashPro5, TCK 10 MHz. PC configuration: Intel i7 at 3.6 GHz, 32 GB RAM, Windows 10.

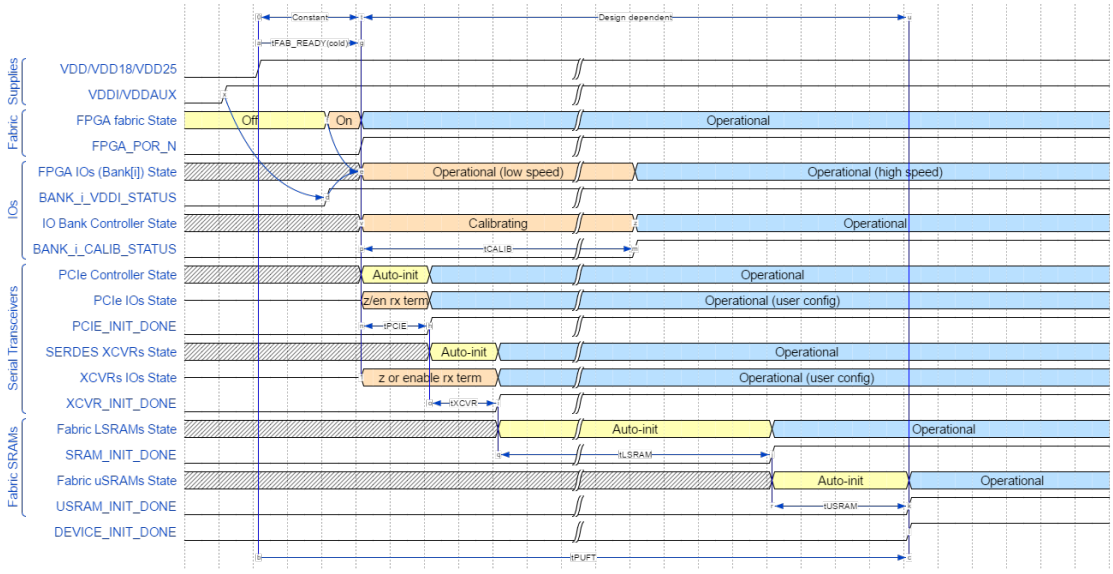
7.9 Power-Up to Functional Timing

Microsemi non-volatile FPGA technology offers the fastest boot-time of any mid-range FPGA in the market.

7.9.1 Power-On (Cold) Reset Initialization Sequence

The following power-up timing diagram assumes that VDDI and VDDAUX are ramped up to their target voltage before VDD, VDD18 and VDD25, which is a requirement for 300XT.

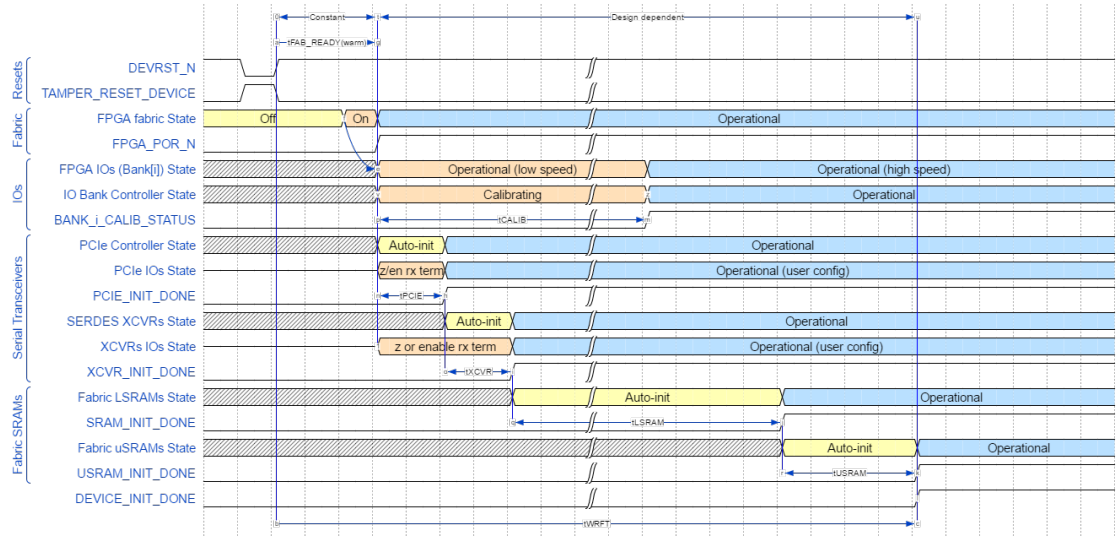
Figure 4 • Cold Reset Timing



7.9.2 Warm Reset Initialization Sequence

The following warm reset timing diagram shows the initialization sequencing of the device when either DEVRST_N or TAMPER_RESET_DEVICE signals are asserted.

Figure 5 • Warm Reset Timing



7.9.3 Power-On Reset Voltages

7.9.3.1 Main Supplies

The start of power-up to functional time (T_{PUFT}) is defined as the point at which the latest of the main supplies (VDD, VDD18, VDD25) reach the reference voltage levels specified in the following table. This starts the process of releasing the reset of the device and powering on the FPGA fabric and IOs.

Table 73 • POR Ref Voltages

Supply	Power-On Reset Start Point (V)	Note
VDD	0.95	Applies to both 1.0 V and 1.05 V operation.
VDD18	1.71	
VDD25	2.25	

7.9.3.2 IO-Related Supplies

For the IOs to become functional (for low speed, sub 250 MHz operation), the (per-bank) IO supplies (VDDI, VDDAUX) must reach the trip point voltage levels specified in the following table and the main supplies (VDD, VDD18, VDD25) above must also be powered on.

Table 74 • IO-Related Supplies

Supply	IO Power-Up Start Point (V)
VDDI	0.85
VDDAUX	1.6

VDDI and VDDAUX of used IO banks must be powered on before VDD, VDD18, and VDD25. For all devices, VDDI3 must be valid at same time as the main supplies. The other IO supplies (VDDI, VDDAUX) have no effect on power-up of FPGA fabric (that is, the fabric still powers up even if the IO supplies of some IO banks remain powered off).

The numbers below and the timing diagrams above assume VDDI, VDDAUX of each IO bank used in the design are already at the trip point.

7.9.4 Design Dependence of Cold Boot and Warm Boot

Some phases of the device initialization are user design-dependent, as the device automatically initializes certain resources to user-specified configurations if those resources are used in the design. It is necessary to compute the overall power-up to functional time by referencing the following tables and adding the relevant phases, according to the design configuration. The following equation refers to timing parameters specified in the above timing diagrams. Please note T_{PCIE} , T_{XCVR}, $T_{LSRAM,}$ and T_{USRAM} can be found in the PolarFire FPGA device power-up and resets user guide UG0725.

$T_{PUFT} = T_{FAB\_READY(cold)} + \max((T_{PCIE} + T_{XCVR} + T_{LSRAM} + T_{USRAM}), T_{CALIB})$

$T_{WRFT} = T_{FAB\_READY(warm)} + \max((T_{PCIE} + T_{XCVR} + T_{LSRAM} + T_{USRAM}), T_{CALIB})$

Note: T_{PCIE}, T_{XCVR}, T_{LSRAM}, T_{USRAM} and T_{CALIB} are common to both cold and warm reset scenarios.

Auto-initialization of FPGA (if required) occurs in parallel with IO calibration. The device may be considered fully functional only when the later of these two activities has finished, which may be either one, depending on the configuration, as may be calculated from the following tables.

7.9.5 Cold Reset to Fabric and IOs (Low Speed) Functional

The following table specifies the minimum, typical, and maximum times from the power supplies reaching the above trip point levels until the FPGA fabric is operational and the FPGA IOs are functional for low-speed (sub 250 MHz) operation.

The following table specifies the minimum, typical, and maximum times from the negation of the warm reset event until the FPGA fabric is operational and the FPGA IOs are functional for low-speed (sub 250 MHz) operation.

Table 76 • Warm Boot
