About Microsemi

Microsemi, a wholly owned subsidiary of Microchip Technology Inc. (Nasdaq: MCHP), offers a comprehensive portfolio of semiconductor and system solutions for aerospace & defense, communications, data center and industrial markets. Products include high-performance and radiation-hardened analog mixed-signal integrated circuits, FPGAs, SoCs and ASICs; power management products; timing and synchronization devices and precise time solutions, setting the world’s standard for time; voice processing devices; RF solutions; discrete components; enterprise storage and communication solutions, security technologies and scalable anti-tamper products; Ethernet solutions; Power-over-Ethernet ICs and midspans; as well as custom design capabilities and services. The first publication of this document.
Temperature Monitor Using LM99 Temperature Sensor

Microsemi RTG4™ radiation tolerant flash-based FPGAs offer significant performance and flexibility advantages to designers working on satellite systems and other equipment required to perform in high radiation environments. RTG4 employs several radiation hardening by design techniques, which help to achieve a high-level of total ionizing dose (TID) hardness. RTG4 also provides built-in Single Event Transient (SET) and Single Event Upset (SEU) mitigation in critical areas to enable the creation of high reliability designs.

This application note shows how the user can configure an external temperature sensor, to perform RTG4 junction temperature measurements across the internal temp diode, and read the sensor status signals using FPGA fabric logic.

In this application note, Texas instruments LM99 temperature sensor, which is available on the RTG4 development Kit is interfaced with RTG4 FPGA using I2C protocol. LM99 temperature sensor registers are configured through the I2C interface and RTG4 device core temperature is measured. This reference design does not use any soft processor IP. The RTL logic implements the configuration of LM99 temperature sensor and temperature monitoring.

The LM99 is an 11-bit remote diode temperature sensor with a 2-wire system management bus (SMBus) serial interface. The LM99 accurately measures its own temperature and the temperature of a remote diode-connected transistor such as the 2N3904 or a thermal diode commonly found on graphics processor units (GPU), computer processor units (CPU or other ASICs). For more information about LM99 temperature sensor, see LM99 info page.

LM99 provides the following set points and status signals:

LM99 set points are:

- Low set point: low temperature alert threshold, asserts ALERT signal if the RTG4 FPGA Core temperature is below this value.
- High set point: high temperature alert threshold, asserts ALERT signal if the RTG4 FPGA Core temperature is above this value.
- T_CRIT set point: critical temperature alert threshold, asserts T_CRIT and ALERT signals if the RTG4 FPGA Core temperature exceeds this value.

LM99 status signals are:

- ALERT: active-Low output signal used as Controller Interrupt or Alert Line.
- T_CRIT: active-Low output signal can be used for system shutdown and also can be used as a status signal. Assertion of this signal is based on the Critical set point value.

These status signals can be monitored and used in the RTG4 FPGA Application. In this reference design, PLL is reset based on the set values of temperature.

The design can be programmed using any of the following options:

- **Using the job file**: To program the device using the job file provided along with the design files, see Appendix: Programming the Devices Using FlashPro Express, page 13.
- **Using Libero SoC**: To program the device using Libero SoC, see Libero Design Flow, page 6.
2.1 Design Requirements

The following table lists the hardware and software required to measure RTG4 temperature monitoring using LM99.

Table 1 • Resource Requirements

1. A Libero Platinum license is required to evaluate the design on the RTG4 device.

2.2 Prerequisites

Before you start:

1. For background information about resetting PLL, see CN19009 RTG4 PLL Lock Stability.
2. Download the temperature rise window calculator from the following location to arrive at the temperature windows that is required as input for this reference design. https://www.microsemi.com/document-portal/doc_download/1244318-rtg4-pll-calculator-files-zip
3. Download the design files from the following location: https://soc.microsemi.com/download/rsc/?f=rtg4_ac487_liberosocv12p1_df
4. Download and install Libero SoC v12.1 on the host PC from the following location. https://www.microsemi.com/product-directory/design-resources/1750-libero-soc#downloads. The latest versions of ModelSim and Synplify Pro are included in the Libero SoC installation package.

2.3 Demo Design

The following figure shows the RTG4 Temperature Monitor block diagram.

Figure 1 • Block Diagram
RTG4 FPGA is interfaced with an external LM99 temperature sensor through I2C protocol for monitoring the temperature of the RTG4 Core. Temperature diode points (D+ and D-) and status signals of LM99 are connected to RTG4 FPGA.

2.4 Design Implementation

The following figure shows the top-level Libero design of RTG4-LM99 temperature measurement.

Figure 2 • Top-Level Libero Design

2.4.1 RTG4_LM99

This block receives set points from the GUI and configures the LM99 register using I2C. The temperature of RTG4 device core is read from LM99 through I2C and displayed in the GUI. This block also includes the logic to reset the PLL (RTG4FCCC_C2_0) based on the ALERT and T_CRIT status signals of LM99. These signals assert depending on the temperature set point provided by the user. It also resets the PLL if the temperature variation is more than 60 °C. For more information about PLL lock stability, see CN19009 RTG4 PLL Lock Stability. The RTL logic in this module can read and write the LM99 register using COREI2C, which is controlled by I2C master RTL logic.

2.4.2 DATA_HANDLE

This block handles data flow between FPGA and GUI Interface for LM99 set point transfers, temperature data and status signals transfers. A COREUART IP configured for 115200 baud rate and a UART interface fsm is used to communicate from FPGA to the GUI in the host PC.

2.4.3 RTG4FCCC_C0_0

This block uses GPDs to get 10 MHz and 25 MHz clock generated from 50 MHz RC oscillator without using PLL.

2.4.4 RTG4FCCC_C2_0

This block uses PLL to generate 100 MHz from 25 MHz clock. The lock signal of this block is monitored by the RTG4_LM99.
2.4.5 Input and Output Signals

The following table lists the input and output signals of the design.

<table>
<thead>
<tr>
<th>Signals</th>
<th>Direction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEVRST_N</td>
<td>Input</td>
<td>Device reset</td>
</tr>
<tr>
<td>ALERT</td>
<td>Input</td>
<td>Active low status signal coming from LM99. Assertion is based on High and Low set points of LM99.</td>
</tr>
<tr>
<td>T_CRIT</td>
<td>Input</td>
<td>Active low status signal coming from LM99. Assertion is based on T_CRIT set point of LM99.</td>

<td>Lock signal change counter. Based on deassertion of Lock signal, this counter increments.</td>
</tr>
</tbody>
</table>

2.4.6 Clocking Structure

In this reference design, there are two clock-domains. From 50 MHz RC oscillator, 10 MHz and 25 MHz are generated using RTG4 Clock Conditioning Circuit (CCC) General Purpose Dividers (GPDs) only. 10 MHz is used for GUI interface and LM99 communication. 25 MHz is fed to a CCC PLL that generates 100 MHz clock for user logic. All the blocks (RTG4_LM99_0 and DATA_HANDLE_0) are using synchronous reset.

2.4.7 Reset Structure

In this reference design, there is only one reset, which is derived form SYSRESET macro which is then synchronized with reset synchronizer block and fed to other blocks.
This chapter describes the Libero design flow of the demo design. The Libero design flow involves the following steps:

- Synthesize
- Place and route
- Verify Timing
- Generate Bitstream
- Run PROGRAM Action

The following figure shows these options in the Design Flow tab.

Figure 5 • Libero Design Flow Options

3.1 Synthesize

To synthesize the design:

1. From the Design Flow window, double-click Synthesize.
   When the synthesis is successful, a green tick mark appears as shown in Figure 5, page 6.

2. Right-click Synthesize and select View Report to view the synthesis report and log files in the Reports tab.
3.2 Place and Route

From the Design Flow window, double-click Place and Route. When place and route is successful, a green tick mark appears as shown in Figure 5, page 6.

Right-click Place and Route and select View Report to view the place and route report and log files in the Reports tab.

3.2.1 Resource Utilization

The following tables list the resource utilization of this design after place and route. These values may vary slightly for different Libero runs, settings, and seed values.

<table>
<thead>
<tr>
<th>Type</th>
<th>Used</th>
<th>Total</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>4LUT</td>
<td>954</td>
<td>151824</td>
<td>0.63</td>
</tr>
<tr>
<td>DFF</td>
<td>378</td>
<td>151824</td>
<td>0.25</td>
</tr>
<tr>
<td>I/O Register</td>
<td>0</td>
<td>2154</td>
<td>0.00</td>
</tr>
<tr>
<td>Logic Element</td>
<td>984</td>
<td>151824</td>
<td>0.65</td>
</tr>
</tbody>
</table>

3.3 Verify Timing

To verify timing:

1. From the Design Flow window, double-click Verify Timing.
2. Right-click Verify Timing and enable all the four corners for timing analysis and constraints coverage report.
3. When the design successfully meets the timing requirements, a green tick mark appears as shown in Figure 5, page 6.
4. Right-click Verify Timing and select View Report to view the verify timing report and log files in the Reports tab.

3.4 Generate FPGA Array Data

To generate the FPGA array data:

1. Double-click Generate FPGA Array Data from the Design Flow window.
2. A green tick mark is displayed after the successful generation of the FPGA array data as shown in Figure 5, page 6.

3.5 Generate Bitstream

To generate the bitstream:

1. Double-click Generate Bitstream from the Design Flow tab.
   When the bitstream is successfully generated, a green tick mark appears as shown in Figure 5, page 6.
2. Right-click Generate Bitstream and select View Report to view the corresponding log file in the Reports tab.
3.6 Run PROGRAM Action

After generating the bitstream, the RTG4 device must be programmed. Follow these steps to program the RTG4 device:

1. Ensure that the following jumper settings are set on the board.

   Table 4 • Jumper Settings

<table>
<thead>
<tr>
<th>Jumper</th>
<th>Pin From</th>
<th>Pin To</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>J11, J17, J19, J23, J26, J21, J32, and J27</td>
<td>1</td>
<td>2</td>
<td>Default</td>
</tr>
<tr>
<td>J16</td>
<td>2</td>
<td>3</td>
<td>Default</td>
</tr>
<tr>
<td>J33</td>
<td>1</td>
<td>2</td>
<td>Default</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

Note: Ensure that power supply switch SW6 is switched OFF while connecting jumpers on RTG4 development kit.

2. Connect the host PC to the J47 connector using the USB cable.
3. Connect the power supply to J9 connector and switch ON the power supply switch, SW6.

Note: You can also program the device using FlashPro Express. See Appendix: Programming the Devices Using FlashPro Express, page 13.

When the device is programmed successfully, a green tick mark appears as shown Figure 5, page 6. The device is successfully programmed, see Running the Demo, page 9.

Figure 6 • Board Setup
This chapter describes how to install and use the GUI to run the temperature monitor demo.

4.1 Installing the GUI

To install the GUI:

1. Extract the contents of the rtg4_ac487_liberosocv12pl_df.rar file. From the rtg4_ac487_liberosocv12pl_df\GUI folder, double-click the setup.exe file.
2. Follow the instructions displayed on the installation wizard.

After successful installation, GUI appears on the Start menu of the host PC desktop.

4.2 Running the Demo

Before you start, ensure that the RTG4 FPGA board is programmed.

1. Open the GUI. It automatically connects to the COM port. If the GUI does not connect automatically, reset the device using switch, SW7.
2. Enter the set point values in the GUI. Critical set-point values can be obtained from RTG4 PLL Temperature Rise Window calculator. Enter Critical set-point as “Maximum operating junction temp before PLL unlock” from the PLL Temperature Rise Window calculator, as shown in the following figure. Enter Low Set-point and High Set-Point as user defined values based on requirement.

*Figure 7 • PLL Rise Window Calculator Output*
3. Click **Configure**. RTG4 Core temperature and status signals are shown in the following figure.
ALERT signal shows red if the core temperature exceeds low or high Set point value or if it exceeds Critical set points value. T_CRIT signal show Reds if the core temperature exceeds Critical set points value. Based on assertion of ALERT or T_CRIT a PLL reset will occur. See the following figure.

**Figure 10 • Alert Assertion**
TMP464 is Radiation tolerant version of the temperature sensor intended for Space applications. TMP64 also provides better accuracy. To replace LM99 with TMP64 on the RTG4 Dev kit the following re-work is required:

- **Hardware changes:**
  - Remove LM99 device from the board
  - Remap D+ and D- pins from RTG4 FPGA core to TMP464 D+ and D-

- **Design changes:**
  - Map I2C SDA and SCL pins to any GPIO and connect to TMP464
  - Map the ALERT and TCRIT to any GPIO and connect to TMP464

After performing the above modifications, the reference design provided in this Application Note has also been updated and validated using TMP64 mounted on the RTG4 development kit as shown in the following figure.

*Figure 11 • RTG4 FPGA Board Interface with TMP464 Evaluation Board*

Appendix: Programming the Devices Using FlashPro Express

This section describes how to program the RTG4 device with the .job programming file using FlashPro Express. The .job file is available at the following design files folder location:

rtg4_ac487_liberosocv12p1_df\Programming_Job_File

To program the device, complete the following steps:

1. Ensure that the jumper settings on the board are the same as those listed in Table 4, page 8.
   **Note:** The power supply switch must be switched off while making the jumper connections.

2. Connect the power supply cable to the J9 connector.
3. Connect the USB cable from the host PC to the J47 (FTDI port).
4. Power ON the board using the SW6 slide switch.
5. On the host PC, launch the FlashPro Express software.
6. Click **New** or select **New Job Project from FlashPro Express Job** from **Project** menu to create a new job project, as shown in the following figure.

**Figure 12 • FlashPro Express Job Project**
7. Enter the following in the **New Job Project from FlashPro Express Job** dialog box:
   - **Programming job file**: Click **Browse**, and navigate to the location where the .job file is located and select the file. The default location is: `<download_folder>\rtg4_ac487_iberosocv12p1_df\Programming_Job`.
   - **FlashPro Express job project location**: Click **Browse** and navigate to the location where you want to save the project.

   *Figure 13 • New Job Project from FlashPro Express Job*

8. Click **OK**. The required programming file is selected and ready to be programmed in the device.

9. The FlashPro Express window appears as shown in the following figure. Confirm that a programmer number appears in the Programmer field. If it does not, confirm the board connections and click **Refresh/Rescan Programmers**.

   *Figure 14 • Programming the Device*
10. Click **RUN** to program the device. When the device is programmed successfully, a **RUN PASSED** status is displayed as shown in the following figure. To run the demo, see Running the Demo, page 9 section.

*Figure 15 • FlashPro Express—RUN PASSED*

![FlashPro Express—RUN PASSED](image)

11. Close **FlashPro Express (Project > Exit)**.
In order to calibrate the errors introduced by non-ideality of remote temperature diode, the temperature sensor can be calibrated by changing offset registers of LM99. User can change the LM99 Remote Temperature Offset High Byte (RTOHB-Address: 0x11) register based on the offset required. Power-on default value of RTOHB is 0. The offset value must be entered in Two's complement format.

For more information, see *LM99 Datasheet*. 
This section lists documents that provide more information related to LM99 temperature sensor.

- For more information about Texas instruments LM99 temperature sensor, see RTG4 development Kit.
- For more information about LM99 temperature sensor, see LM99 Product page.
- For more information about TMP464 radiation tolerant temperature sensor, see TMP464 Product page.
