Introduction

Real-time clocks are used in a wide variety of applications. For example, a real-time clock is used to time stamp particular transactions done on ATM machines or vending machines, such as data transfers.

Real-time clocks is used to record the active run/on time for appliances, industrial machinery, and similar devices.

Common requirements for real-time clocks include the following capabilities:

- Presetting the real-time clock at any time
- Tracking the time when the application is in standby mode

The Microsemi Fusion® field programmable gate arrays (FPGAs) provide the means to easily implement a real-time clock within the FPGA with both of the above-mentioned capabilities. The analog block of Fusion FPGAs contains a real-time counter (RTC) that runs off the analog 3.3 V supply. The RTC block in Fusion devices contains a 40-bit counter along with a 40-bit match register and a control register that oversees the functionality of the counter. [Figure 1 on page 2](#) shows an example of implementation of the match for real-time clock. The clock to the counter is provided by an external crystal. The crystal clock is pre-scaled (divided by 128) internally before entering the counter. As a result, if the crystal clock is chosen to 32.768 kHz, 7-bit of the counter is toggle at a rate of one Hz (one second) and the whole counter equates to just over 136 years of elapsed timekeeping.

The RTC of Fusion FPGAs provides the following capabilities:

- FPGA fabric can read from and write to the 40-bit count register of RTC.
- FPGA fabric can read from and write to the 40-bit match register.
- The overall match output or individual match bits are available to the FPGA fabric.
- FPGA fabric can read from and write to the RTC control register. This enables the user to perform count enable/disable or counter reset dynamically during normal operation.

These characteristics and capabilities of the Fusion RTC make this block an ideal choice for applications using a real-time clock. By using the RTC block of Fusion devices, the real-time clock application can be integrated into the FPGA, reducing the cost/size of the application hardware.

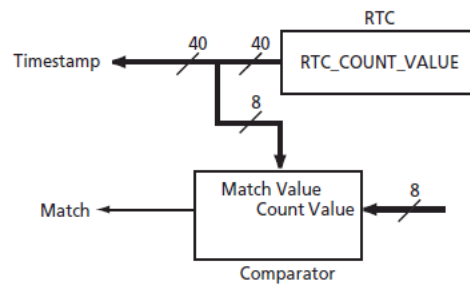

Figure 1 • Generating Match Signal from RTC Register Content

Implementation

If the crystal oscillator, driving the RTC block of Fusion FPGAs, is set to 32.768 kHz, 7-bit of the RTC block is toggle at the rate of one Hz. The contents of the first byte of the RTC count register can be accessed using the SmartGen IP. 7-bit of the RTC creates a one Hz periodic signal for the FPGA fabric. This signal can drive specific counters, implemented in the FPGA fabric by users, in which the seconds, minutes, hours, days, months, or years reside.

Real-Time Clock Preset

The register inside the FPGA fabric holding the real-time clock value can be preset (written) to a user defined value at any time. Furthermore, the RTC count register can be preset to a user-defined value if needed, using SmartGen IP. Real-time clock implementations in which only 7-bit of the RTC is used to create one Hz pulses to the FPGA fabric do not need to write into the RTC. In such applications, presetting the clock only requires writing into the FPGA fabric registers in which the time is stored.

Real-Time Clock in Standby Mode

In many low power applications, the FPGA fabric enters and exits standby mode by powering down the 1.5 V supply to the FPGA fabric. The RTC block is powered by the external 3.3 V supply, and therefore it keeps counting during standby mode. Consequently, the content of the RTC provides information of the elapsed time in standby mode.

If a user application requires the real-time clock to be automatically updated after exiting standby mode, the current real-time must be stored in the embedded Flash memory before entering standby mode. When the 1.5 V supply to the FPGA fabric is powered up again, the last content of the real-time clock registers is retrieved from the embedded Flash memory and adjusted based on the elapsed time extracted from RTC. Then the updated time can be preset into the FPGA fabric registers and the real-time clock continues to operate as normal based on the one Hz pulses coming from RTC.

Figure 2 shows the block diagram implementation of a complete real-time clock system with standby mode and preset features.

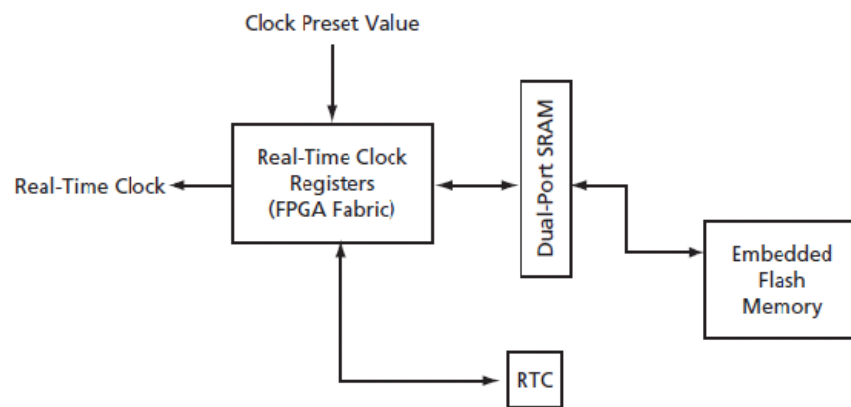

Figure 2 • Block Diagram of Real-Time Clock System Implementation

Conclusion

The Microsemi Fusion FPGAs contain a real time counter, which can be simply converted to a real-time clock. The counter is powered by a 3.3 V supply and therefore operates independently from the FPGA fabric power supply. This separation allows the RTC to control the power supply to the FPGA core, enabling a robust standby mode capability. The RTC block in Fusion FPGAs allows designers to integrate a complete real-time clock application with the desired set of features into the FPGA.

List of Changes

The following shows important changes made in this document for each revision.

Revision	Changes	Page
Revision 2 (July 2016)	Non-technical updates.	N/A
Revision 1 (June 2006)	The low power modes of operation were updated and clarified.	N/A
Revision 0 (December 2005)	Initial release.	N/A

About Microsemi

Microsemi Corporation (Nasdaq: MSCC) offers a comprehensive portfolio of semiconductor and system solutions for aerospace & defense, communications, data center and industrial markets. Products include high-performance and radiation-hardened analog mixed-signal integrated circuits, FPGAs, SoCs and ASICs; power management products; timing and synchronization devices and precise time solutions, setting the world's standard for time; voice processing devices; RF solutions; discrete components; enterprise storage and communication solutions, security technologies and scalable anti-tamper products; Ethernet solutions; Power-over-Ethernet ICs and midspans; as well as custom design capabilities and services. Microsemi is headquartered in Aliso Viejo, Calif., and has approximately 4,800 employees globally. Learn more at www.microsemi.com.
