Purpose

This application note describes the techniques for improving the efficiency of double data rate (DDR) controller using an example design for the SmartFusion[®]2 Advanced Development Kit board. It also provides details about implementing the DDR synchronous dynamic random access memory (SDRAM) simulation flow using the Micron[®] DDR3 SDRAM model and Microsemi[®] DDR3 SDRAM verification IP (VIP) model.

Introduction

The SmartFusion2 device has two high-speed hardened application-specific integrated circuit (ASIC) memory controllers such as microcontroller subsystem (MSS) DDR (MDDR) and fabric DDR (FDDR) for interfacing with the DDR2, DDR3, and low power DDR1 (LPDDR1) SDRAM memories. The MDDR and FDDR subsystems are used to access high-speed DDR memories for high-speed data transfer and code execution.

The DDR memory connected to the MDDR subsystem can be accessed by the MSS masters and the master logic implemented in the FPGA fabric master, whereas the DDR memory connected to the FDDR subsystem can be accessed only by an FPGA fabric master. The FPGA fabric masters communicate with the MDDR and FDDR subsystems through the AXI or AHB interfaces.

Figure 1 illustrates the MDDR data path for AXI/AHB interface.

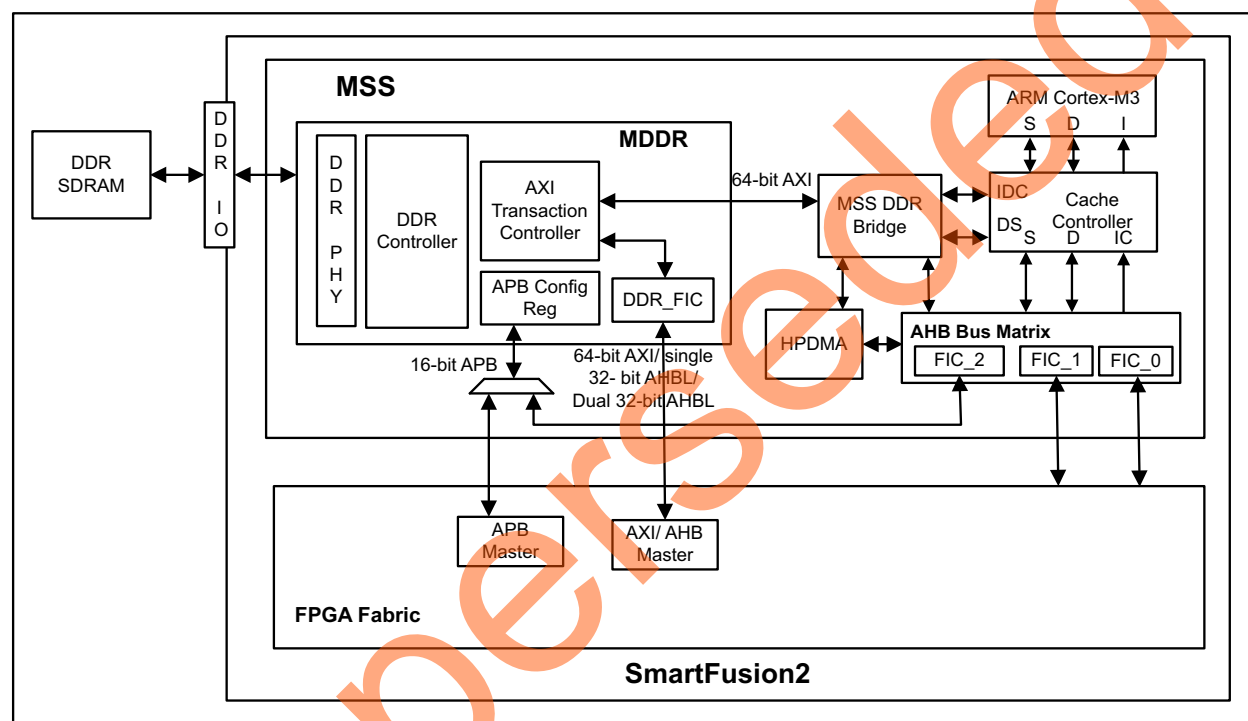

Figure 1 • MDDR Data Path for AXI/AHB Interfaces

The AXI interface is used for burst transfers that provide an efficient access path and high throughput. Though the throughput is dependent on many system level parameters, it can be improved by applying specific optimization techniques. For more information on MDDR and FDDR subsystems, refer to the [UG0446: SmartFusion2 and IGLOO2 FPGA High Speed DDR Interfaces User Guide](#).

The sample design consists an AXI master, LSRAM, and counters for throughput measurement. During the write operation, the AXI master reads the LSRAM and writes to the DDR3 memory and measures the throughput. During the read operation, the AXI master reads the DDR3 memory and writes to LSRAM and measures the throughput. The throughput values are displayed on the host PC using the universal asynchronous receiver/transmitter (UART) interface.

Following are the types of memory simulation models that can be used:

- **Microsemi provided generic DDR memory simulation model (VIP):** The Libero® System-on-Chip (SoC) includes a JEDEC compliant VIP model. The VIP model is attached to the pin side of the MDDR/FDDR subsystem and simulates the functionality of a DDR memory device. It can be configured for the DDR2, DDR3, and LPDDR SDRAM memories and used to complement vendor models or to act as a substitute in case a vendor model is not available.
- **Vendor-specific memory model:** Memory vendors such as Micron, Samsung, and Hynix provide downloadable simulation models for specific memory devices. Ensure that the downloaded simulation model is JEDEC compliant.

This document also describes the DDR SDRAM simulation flow using the Micron DDR3 SDRAM and Microsemi DDR3 SDRAM VIP models.

Design Requirements

Table 1 lists the design requirements.

Table 1 • Design Requirements

Design Requirements	Description
Hardware Requirements	
SmartFusion2 Advanced Development Kit	Rev B or later
Host PC or Laptop	Any 64-bit Windows Operating System
Software Requirements	
Libero SoC	v11.6
SoftConsole	v3.4 SP1

Optimization Techniques

This section describes the following optimization techniques:

- Frequency of Operation
- Burst Length
- AXI Master without Write Response State
- Read Address Queuing
- Series of Writes or Reads
- DDR Configuration Tuning

Frequency of Operation

The MDDR and FDDR subsystems support clock management dividers inside the embedded block. The divider ratios can be selected from the Clock Configurator for DDR clocks (MDDR_CLK/FDDR_CLK) and DDR_FIC clock. The best overall throughput ratio is 2:1, that is, half the DDR clock frequency. Many other ratios are possible to provide flexibility to the FPGA design. To show the optimal data throughput, this application note shows all examples using the 2:1 ratio. The design example uses 64-bit AXI as an FPGA fabric interface and is configured to use 333.33 MHz as DDR clock frequency and 166.66 MHz as AXI clock. 166.66 MHz is the fastest clock frequency rate available to run the MDDR_CLK, as this is the limit of the MSS CLK_BASE.

Burst Length

The MDDR and FDDR subsystems support the DRAM burst lengths of 4, 8, or 16, depending on the configured bus-width and the DDR type. The AXI transaction controller in the MDDR and FDDR subsystems supports up to 16-beat burst read and write. The AXI beat burst length (write and read) and burst length of DRAM affect the optimal performance, however, setting the maximum supported burst length for DDR SDRAM and AXI interface achieves the optimal performance. The design example uses a DDR SDRAM burst length of 8 and an AXI write and read beat burst length of 16.

Note: The design example is designed to run on the SmartFusion2 Advanced Development Kit board, which has the SmartFusion2 M2S150 device and a DDR3 SDRAM from Micron with the part number; MT41K256M8DA -125. Both the devices support the maximum burst length of 8.

AXI Master without Write Response State

When AXI master sends the last data (D (A15)), the WLAST signal goes HIGH, indicating that it is the last transfer in the first write burst. When AXI slave in DDR subsystem accepts all the data items, it drives a write response (BVALID) back to the master to indicate that the write transaction is complete. By AXI protocol, AXI master must wait for the write response before initiating the next write transaction. However, the time spent waiting for the write response reduces the overall throughput as the clock cycles are not used. AXI master can send the second burst write address (B) without waiting for the write response of the first burst. This improves the write throughput by decreasing the wait states.

This application note is focused on optimal throughput, and therefore, the write response channel is not verified. Microsemi recommends that when using this technique the write response channel is used concurrently with starting the next transfer to ensure that the previous write data is fully accepted. The AXI protocol has a defined methodology for handling the termination of write burst transaction. This must be followed if the write response channel returns an incorrect value.

Figure 2 illustrates the write transaction timing diagram without the write response state.

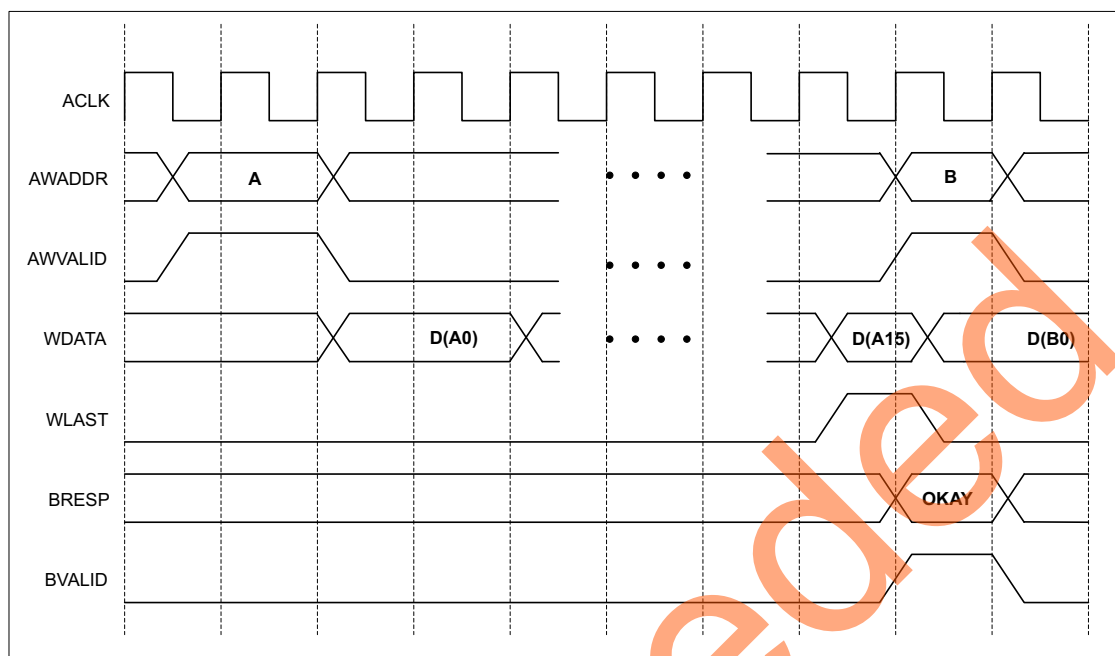

Figure 2 • Write Transaction Timing Diagram without Write Response State

Read Address Queuing

The MDDR and FDDR subsystems support up to four outstanding read transactions. In 2:1 clock ratio, the MDDR controller starts the burst read transaction before the command FIFO full, which allows AXI master to send five burst read addresses.

Figure 3 illustrates the burst read address queuing timing diagram.

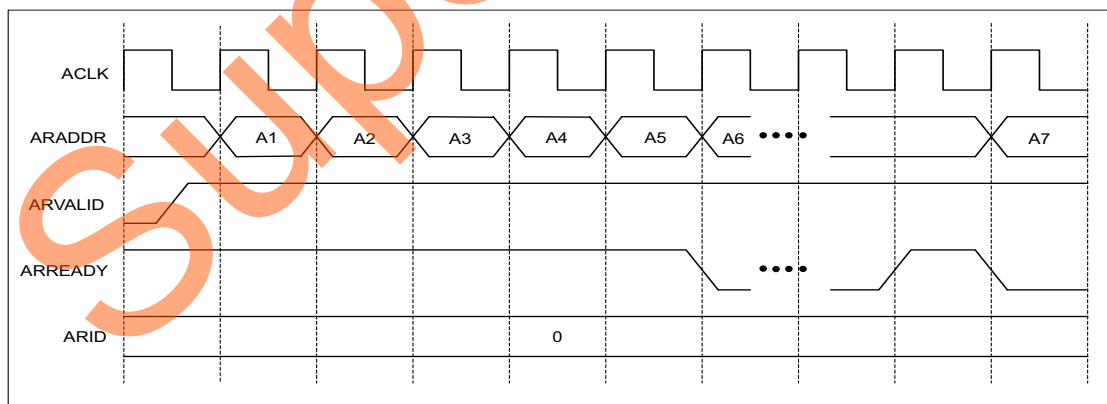

Figure 3 • Read Transaction Timing Diagram with Burst Read Address Queuing

AXI master increments the burst read address as long as AXI slave in the DDR subsystem asserts the ARREADY signal. The burst read address queuing significantly increases the read throughput compared to the normal AXI read sequence. Table 7 on page 35 and Table 8 on page 36 show this significant improvement. Read address queuing does not reduce the initial latency associated with a DDR memory read access. By issuing multiple reads in sequence, the initial latency is only accounted for the first read. After the first read data is returned to the remainder of the requested data, the requested data is returned in sequence without a large read access penalty associated with the first read.

Series of Writes or Reads

The MDDR and FDDR subsystems' performance depend on the method of data transfer between the DDR SDRAM and AXI master. The following methods of data transfer reduce optimal performance:

- Single beat burst read and write operation
- Random read and write operation
- Switching between read and write operation

The MDDR and FDDR subsystems' performance increase while performing a series of reads or writes from the same bank and row. Figure 4 illustrates the AXI to DDR3 address mapping for the DDR3 SDRAM on the SmartFusion2 Advanced Development Kit board.

Figure 4 • AXI to DDR3 Address Mapping

When the AXI address crosses 0x0800, the DDR subsystem activates Row 0 of Bank 1. Row 1 of Bank 0 is activated only when the AXI address crosses 0x4000. If a new row is accessed every time, it must be pre-charged first. This means that additional time is needed before a row can be accessed and this reduces the overall throughput. Understanding the internal memory layout of the DDR and how it maps to the AXI address enables the accesses to minimize the row changes and increases the overall throughput.

DDR Configuration Tuning

The DDR SDRAM datasheet provides the timing parameters required for the proper operation in terms of time units. These timings must match the configuration registers in the MDDR/FDDR controller. The timing parameters are required as number of DDR clock cycles and these are entered in the DDR configurator GUI. The selection of minimum write or read delay values can result in optimal performance. Implementing this approach requires extensive memory testing to ensure that the memory transfers are stable.

The SmartFusion2 Advanced Development Kit DDR3 is supplied with a default configuration file to setup the MDDR controller, which is available on its documentation web page.

Table 2 lists the tuned parameters for better performance than the values in the default configuration file.

Table 2 • Tuned DDR Timing Parameters

Parameters	Default Values	Tuned Values
CAS	6 (clk)	5
RAS min	15	12
RAS max	8192	22528
RCD	6 (clk)	5
RP	7 (clk)	5

FAW	32	10

Implementation on the SmartFusion2 Device

The optimization techniques that are mentioned in the preceding section are implemented and validated using the SmartFusion2 Advanced Development Kit board. This section describes the following:

- [Design Description](#)
- [Hardware Implementation](#)
- [Software Implementation](#)
- [Running the Design](#)

Design Description

The design consists MSS, CoreConfigP IP, CoreResetP IP, SYSRESET_POR Macro, on-chip 25/50 MHz RC oscillator, Fabric CCC (FCCC), AXI master (AXI_IF), AHB master (AHB_IF), and a command decoder (CMD_Decoder). Figure 5 shows the block diagram of the design.

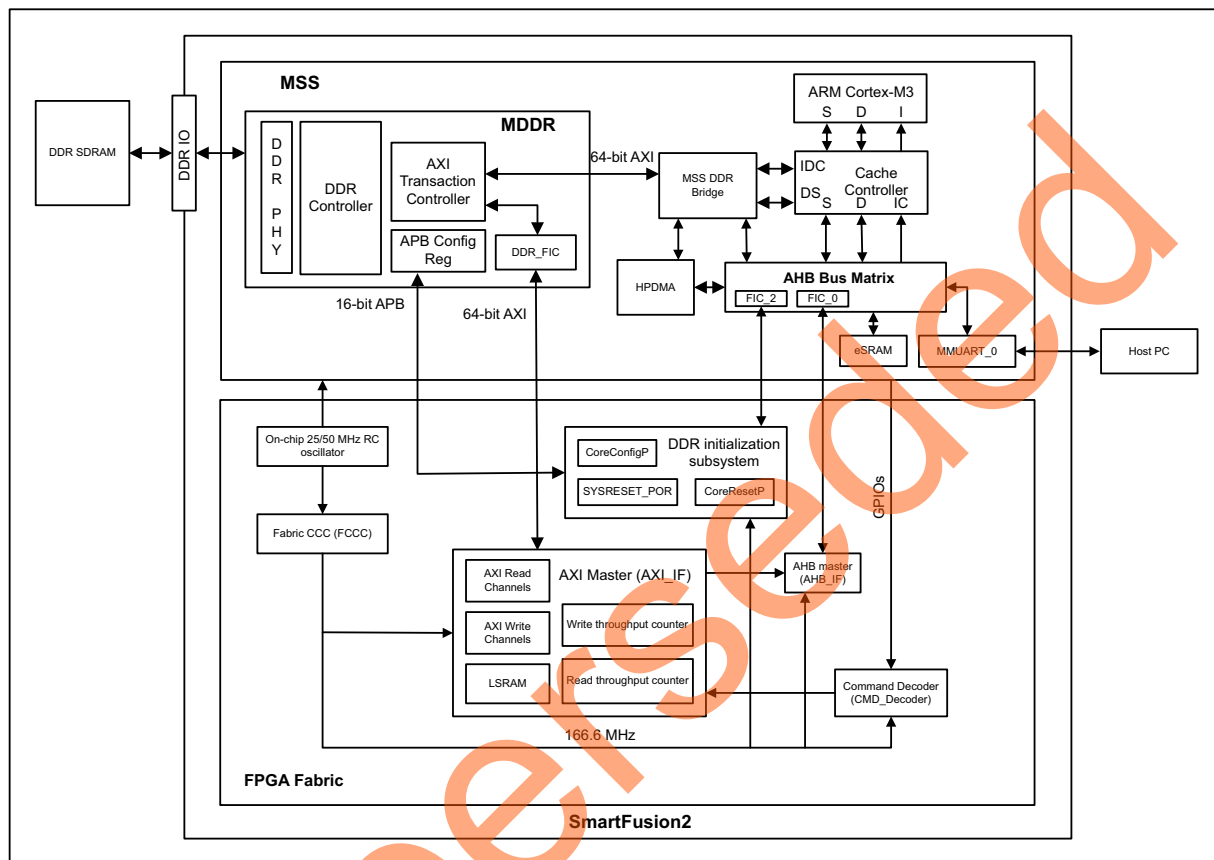

Figure 5 • Top-Level Block Diagram of the Design

MSS is configured to use one UART interface (MMUART_0), MSS clock conditioning circuit (MSS_CCC), RESET Controller, eight GPIOs, one instance of the fabric interface (FIC_0), FIC_2 (Peripheral Initialization), and MDDR.

The FIC_0 interface is configured to use a slave interface with the AHB-Lite (AHBL) interface type. The FIC_2 is configured to initialize the MSS DDR using the ARM® Cortex®-M3 processor along with the CoreConfigP, CoreResetP, and SYSRESET_POR macro. The MMUART_0 is used as an interface for writing to HyperTerminal. Eight GPIOs are configured as output and routed to the FPGA fabric. The Cortex-M3 processor initiates the AXI write and read operation using these GPIOs. The MDDR is configured to use the DDR3 interface and routes the AXI interface to the FPGA fabric.

FCCC is configured to provide the 166.6 MHz reference clock to the MSS_CCC and the fabric logic. The on-chip 25 MHz/50 MHz RC oscillator is the reference clock source for the FCCC.

Table 3 lists the MSS_CCC generated clocks.

Table 3 • MSS_CCC Generated Clocks

Clock Name	Frequency in MHz
M3_CLK	166.6
MDDR_CLK	333.2
DDR_SMC_FIC_CLK	166.6
APB_0	83.3
APB_1	83.3
FIC_0_CLK	166.6

The command decoder receives the AXI transaction control from the Cortex-M3 processor through GPIOs and generates write, read, write size, and read size signals. Figure 6 illustrates the command decoding.

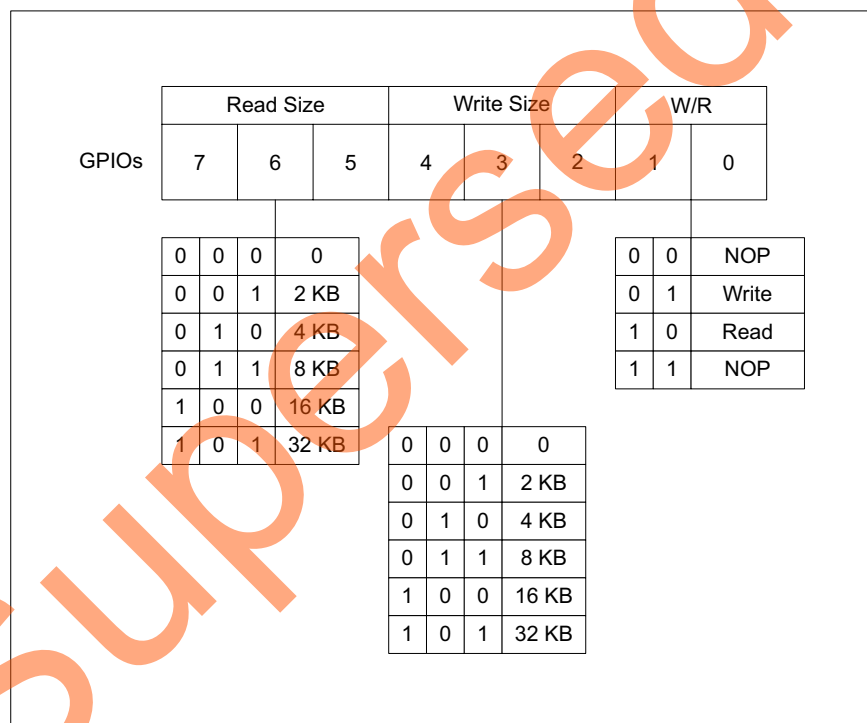

Figure 6 • Command Decoding

AXI master block consists AXI read channel, AXI write channel, write throughput counter, read throughput counter, and 512x64 LSRAM. It performs the write or read operation¹ based on the input signals from the command decoder. During the write operation, AXI master reads the LSRAM and writes into the DDR3 memory, and then measures the write throughput. During the read operation, AXI master reads the DDR3 memory and writes into LSRAM, and then measures the read throughput. The write throughput counter counts the AXI clocks between AWVALID of first data and WLAST of last data. Similarly, the read throughput counter counts the AXI clocks between ARVALID of first data and RLAST of last data. After triggering the write or read operation, the AXI master performs the write or read operation eight times to get the average throughput. During the write operation, the write address (AWADDR) starts from 0x00000000, and is incremented by 128 (16-beat burst). During the read operation, the read address (ARADDR) starts from 0x01000000, and is incremented by 128.

After each write or read operation, AXI master sends the throughput count value and an eSRAM address starting from 0x20008104 to AHBL master. Then, AHBL master writes the throughput values into eSRAM. After that the Cortex-M3 processor reads the values and sends to the host PC using the UART interface.

For more information on creating a custom AXI interface on user logic, refer to the [AC409: Connecting User Logic to AXI Interfaces of High-Performance Communication Blocks in the SmartFusion2 Devices Application Note](#).

For more information on creating a custom AHB interface on user logic, refer to the [AC333: Connecting User Logic to the SmartFusion Microcontroller Subsystem Application Note](#).

For more information on timing optimization performed in the AXI interface, refer to the [UG0446: SmartFusion2 and IGLOO2 FPGA High Speed DDR Interfaces User Guide](#).

1. The write or read operation depends on the size of write or read data. For example, if the write size is selected as 2 KB, then one AXI write operation equals to 16x16-beat burst (16x16x64).

Configuring the System Builder

This section describes how to configure the MDDR and other device features and then build a complete system using the System Builder graphical design wizard in the Libero SoC software. For more information on how to launch and use the System Builder wizard, refer to the [SmartFusion2 System Builder User Guide](#).

The following steps describe how to configure the MDDR and access it from AXI master in the FPGA fabric:

1. Go to the **System Builder - Device Features** tab and select the **MDDR** check box. Leave the rest of the check boxes unchecked, as shown in [Figure 8](#).

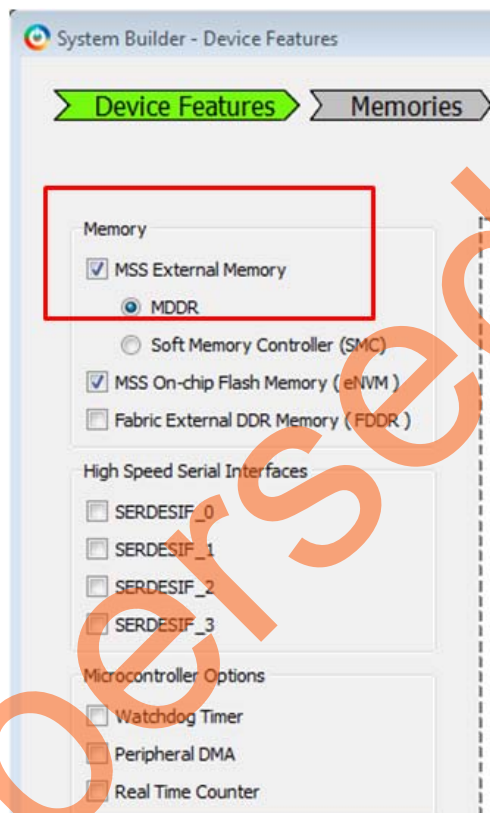

Figure 8 • System Builder - Device Features Tab

2. Configure the MDDR in **Memories** tab as shown in [Figure 9 on page 13](#). In this example, the design is created to access the DDR3 memory with a 16-bit data width and no ECC.
3. Set the DDR memory settling time to 200 μ s and click **Import Configuration** file to initialize the DDR memory. The configuration file is stored in eNVM. The MDDR subsystem registers must be initialized before accessing DDR memory through the MDDR subsystem. The MDDR configuration register file is provided along with the design file (refer "[Appendix: Design Files](#)" on [page 37](#)).

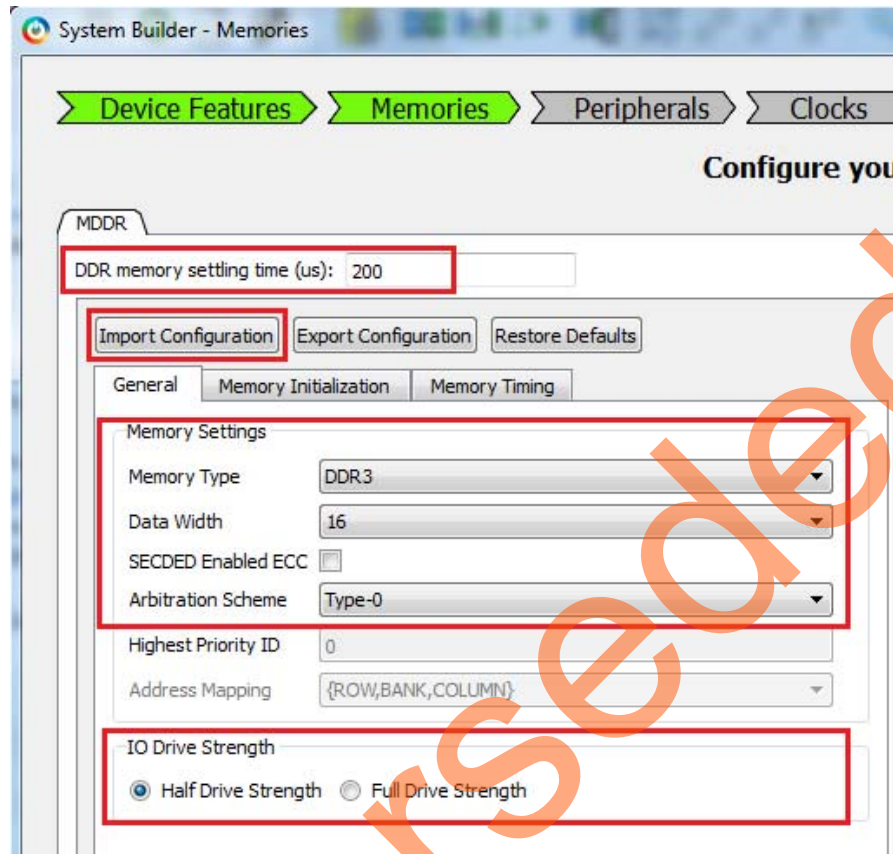

Figure 9 • Memory Configuration

4. In the Peripherals tab, drag **Fabric AMBA Master** to **MSS DDR FIC Subsystem**, as shown in Figure 10. **AMBA_MASTER_0** is added to the subsystem. Configure the Interface Type as **AXI**. Figure 10 shows the Peripherals tab.

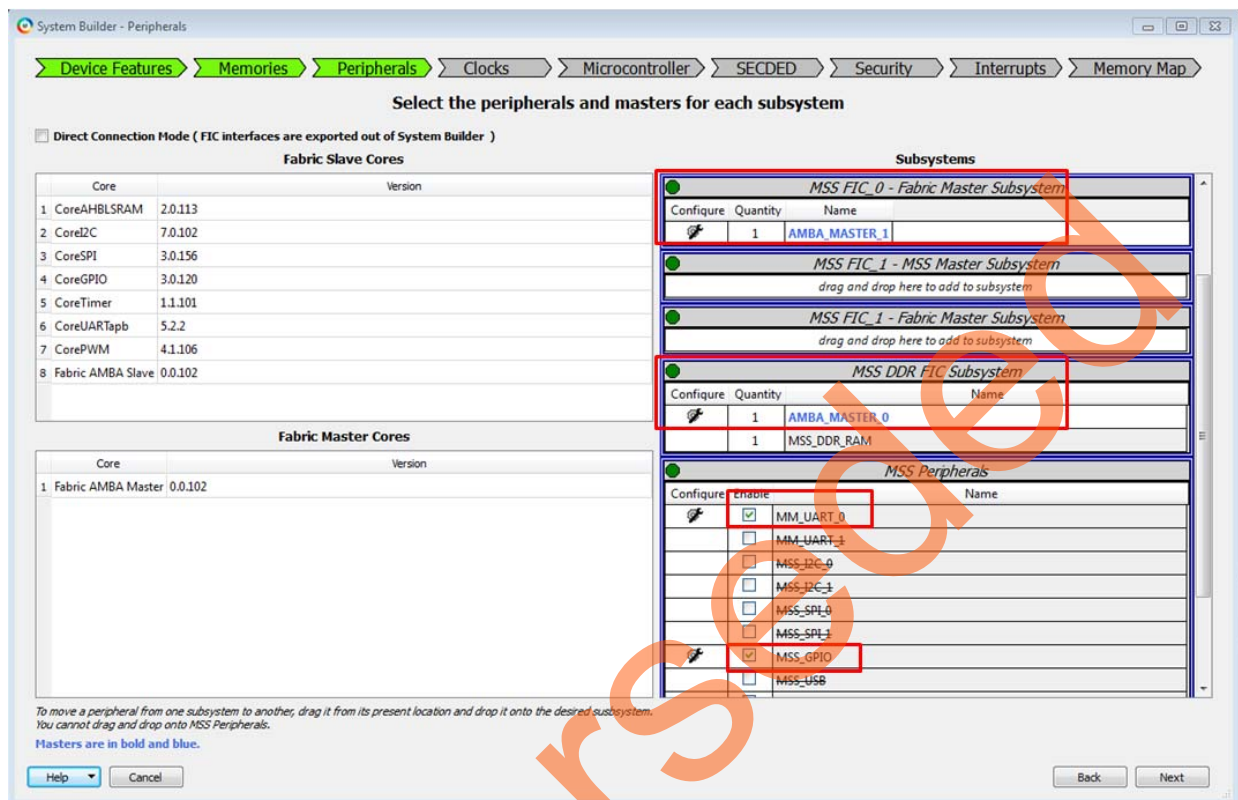

Figure 10 • Selecting MMUART_0 and MSS GPIO in Peripherals Tab

5. Drag **Fabric AMBA Master** to **MSS FIC_0 - Fabric Master Subsystem**. **AMBA_MASTER_1** is added to the subsystem and configured with **AHBLite**.
6. Under **MSS Peripherals**, select **MM_UART_0** and **MSS_GPIO**.

7. Select **IO** under **Connect To** option in the **MM_UART_0 Configuration** window, as shown in Figure 11.

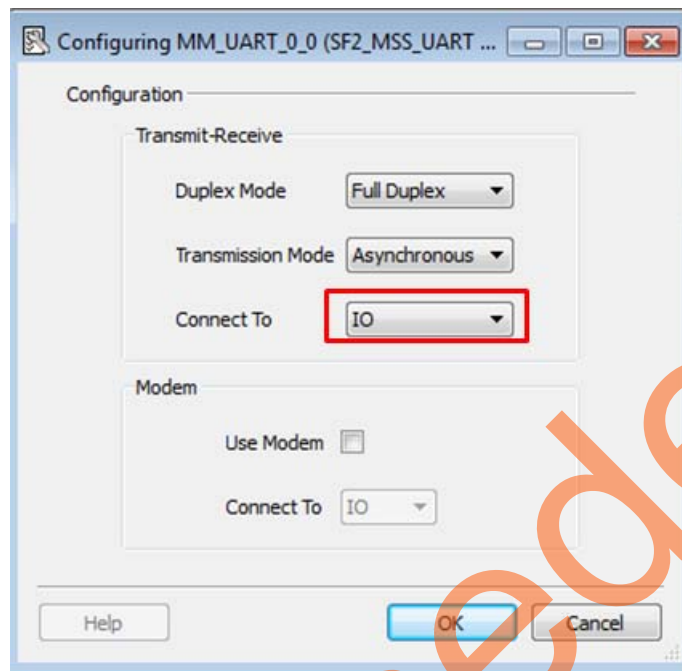

Figure 11 • MM_UART_0 Configuration Window

8. Use the settings in the **MSS_GPIO Configurator** tab, as shown in [Figure 12](#) and keep the remaining at default state. Eight GPIOs are configured as output and routed to the FPGA fabric.

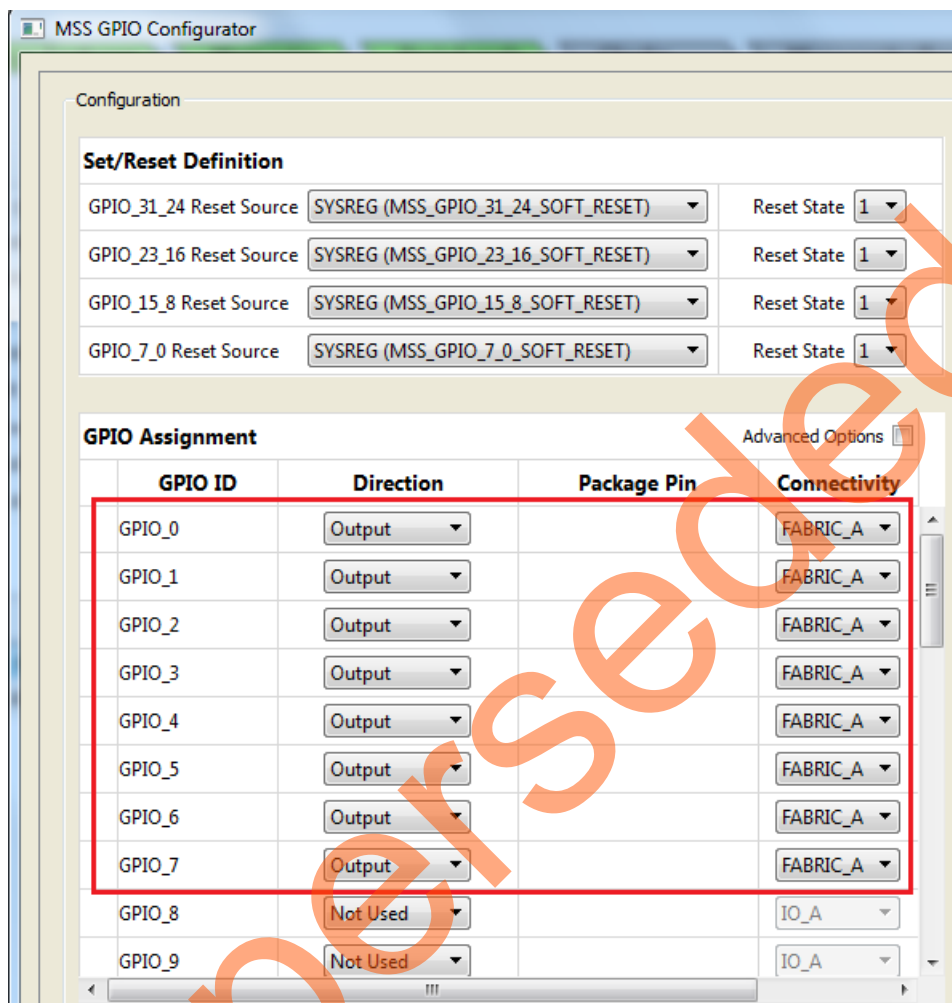

Figure 12 • MSS_GPIO Configuration

9. Configure the System clock and Subsystem clocks in the **Clocks** tab, as listed in [Table 4](#).

Table 4 • System and Subsystem Clocks

Clock Name	Frequency in MHz
System clock	On-chip 25 MHz/50 MHz RC oscillator
M3_CLK	166.6
MDDR_CLK	333.2
DDR/SMC_FIC_CLK	166.6
APB_0_CLK	83.3
APB_1_CLK	83.3
FIC_0_CLK	166.6

Figure 13 shows the **Clocks** configuration window.

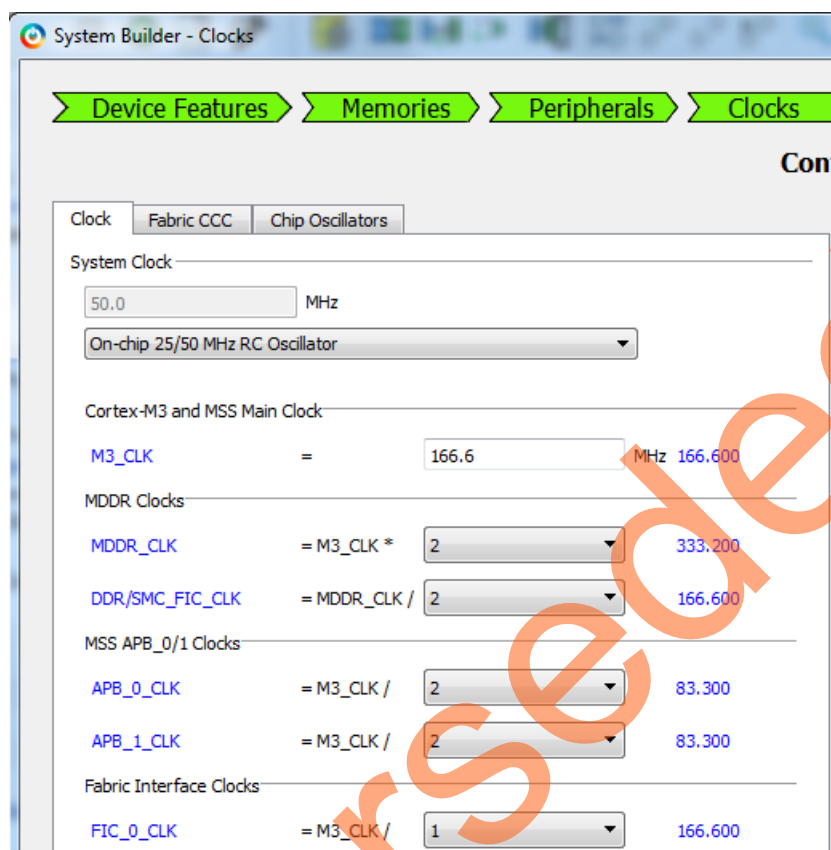

Figure 13 • System and Subsystem Clocks Configuration

10. Follow the remaining steps with default settings and generate the design.
11. Instantiate the custom logic (AXI master, AHB master, and a command decoder) and connect, as shown in Figure 7 on page 11.

Simulation Using Micron DDR3 SDRAM Model

Setting Up the Simulation Model

Setting up and running the simulation involve the following steps:

1. Obtain the Micron DDR3 memory model files - the SmartFusion2 Advanced Development Kit board has the DDR3 SDRAM from Micron with the part number; MT41K256M8DA -125. The memory model used in the example design supports this device (Refer to "Appendix: Design Files" on page 37).
2. Copy the `ddr3.v` and `ddr3_parameters.vh` simulation model files to the `\Libero SoC project directory>\stimulus` directory.
3. Instantiate and connect the DDR3 memory model in the testbench, as shown in Figure 14.

```
ddr3 DDR3_0 (
    .rst_n(MDDR_RESET_N),
    .ck(MDDR_CLK),
    .ck_n(MDDR_CLK_N),
    .cke(MDDR_CKE),
    .cs_n(MDDR_CS_N),
    .ras_n(MDDR_RAS_N),
    .cas_n(MDDR_CAS_N),
    .we_n(MDDR_WE_N),
    .addr(MDDR_ADDR[14:0]),
    .ba(MDDR_BA),
    .dm_tdq(MDDR_DM_RDQS[0]),
    .dq(MDDR_DQ[7:0]),
    .dqs(MDDR_DQS[0]),
    .dqs_n(MDDR_DQS_N[0]),
    .odt(MDDR_ODT),
    .tdqs_n()
);

ddr3 DDR3_1 (
    .rst_n(MDDR_RESET_N),
    .ck(MDDR_CLK),
    .ck_n(MDDR_CLK_N),
    .cke(MDDR_CKE),
    .cs_n(MDDR_CS_N),
    .ras_n(MDDR_RAS_N),
    .cas_n(MDDR_CAS_N),
    .we_n(MDDR_WE_N),
    .addr(MDDR_ADDR[14:0]),
    .ba(MDDR_BA),
    .dm_tdq(MDDR_DM_RDQS[1]),
    .dq(MDDR_DQ[15:8]),
    .dqs(MDDR_DQS[1]),
    .dqs_n(MDDR_DQS_N[1]),
    .odt(MDDR_ODT),
    .tdqs_n()
);
```

Figure 14 • Instantiating Simulation Model

4. Ensure that the `ddr3.v` file is included at the top of the testbench file. The example design uses two instances of DDR3 models with a device width of eight.

- Set the testbench in which DDR3 memory model is instantiated as active stimulus. Figure 15 shows the settings under Stimulus Hierarchy.

Figure 15 • Stimulus Settings

- Click **Project > Project Settings > Simulation Options > Waveforms**. Figure 16 shows the Waveforms settings on the right.

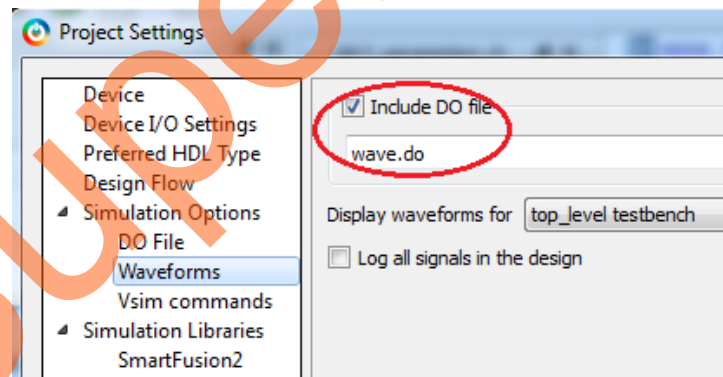

Figure 16 • Waveforms Settings

- Select the **Include DO file** check box and enter **wave.do** in the box, as displayed in Figure 16.

The timing diagrams shown from Figure 17 through Figure 19 illustrate the write operation. Figure 17 illustrates the AXI master signals, command from CMD_Decoder, and address and data to AHB master.

Figure 17 • AXI Master (AXI_IF) Signals for Write Operation

Figure 18 illustrates the MDDR signals. AXI master reads 2 KB of data from LSRAM and writes to DDR3 SDRAM. The write operation is repeated eight times. The data is written into Row 0 of all banks (Bank 0 – Bank 7).

Figure 18 • MDDR Signals for Write Operation

Figure 19 illustrates the AHB master signals. AHB master receives the address and data from AXI master and writes into eSRAM.

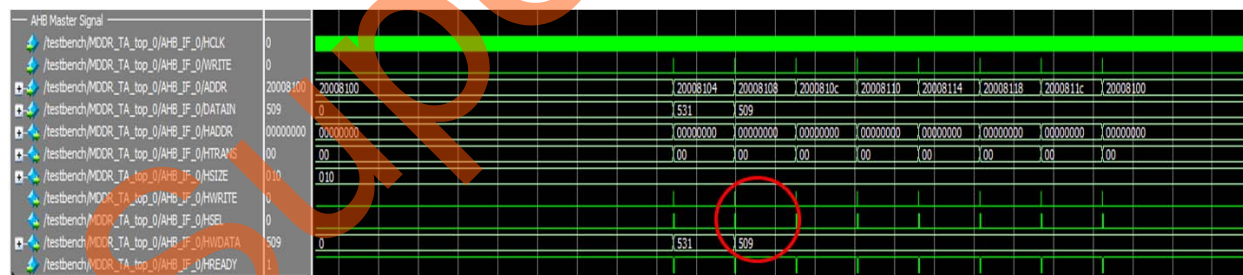

Figure 19 • AHB Master Signals

The timing diagrams shown from Figure 20 through Figure 22 on page 21 illustrate the read operation. Figure 20 illustrates the AXI master signals, command from CMD_Decoder, and address and data to AHB master.

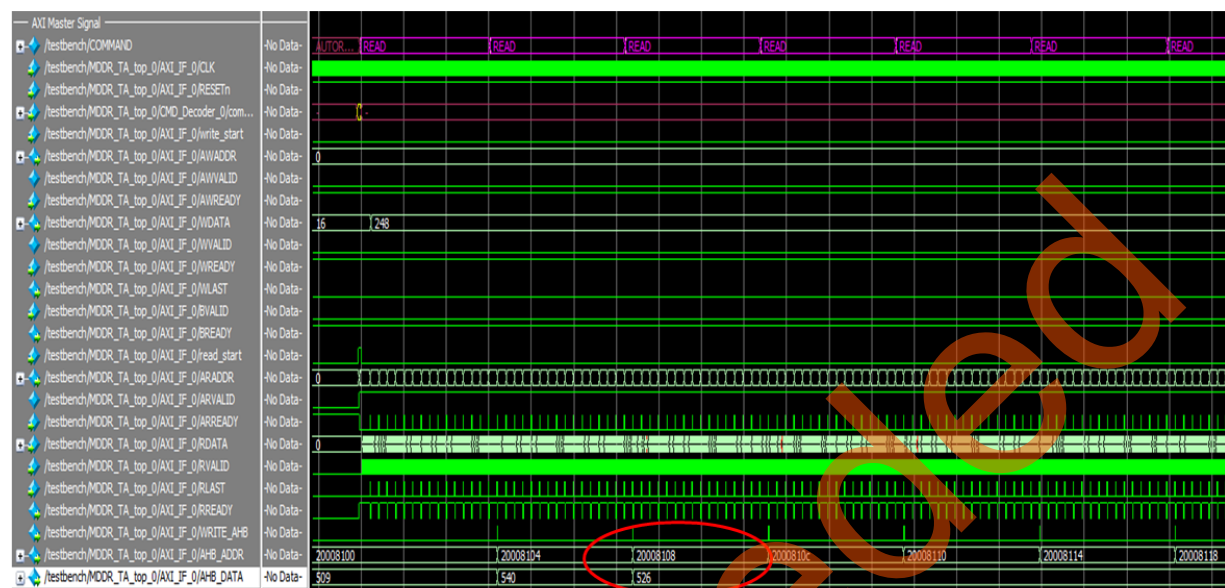

Figure 20 • AXI Master (AXI_IF) Signals for Read Operation

Figure 21 illustrates the MDDR signals. AXI master reads 2 KB of data from DDR3 SDRAM and writes to LSRAM. The read operation is repeated eight times. The data is read from Row 0 of all banks (Bank 0 – Bank 7).

Figure 21 • MDDR Signals for Read Operation

Figure 22 illustrates the AHB master signals. AHB master receives the address and data from AXI master and writes to eSRAM.

Figure 22 • AHB Master Signals

Simulation using Microsemi DDR3 SDRAM VIP Model

Libero SoC includes a generic DDR memory simulation model (VIP). The VIP is attached to the pin side of the MDDR or FDDR subsystem, and simulates the functionality of a DDR memory device. It can be configured for DDR2, DDR3, and LPDDR SDRAM memories as well.

Setting Up Simulation Model

Setting up and running the simulation involve the followings steps:

1. Click **Catalog** tab in the Libero SoC.
2. Select the **Simulation Mode** check box.
3. Under **Memory and Controller**, select **Generic DDR Memory Simulation** model and drag into the SmartDesign testbench canvas. [Figure 23](#) shows the Simulation mode.

Figure 23 • Generic DDR Memory Simulation Model

4. Enter the Generic DDR Memory Simulation model configuration details, as shown in [Figure 24](#). The example design uses two instances of SimDRAM (VIP model) with a device width size of eight.

Figure 24 • Configuring SimDRAM

-

6. Generate the design by clicking **SmartDesign > Generate Component** or by clicking **Generate Component** on the SmartDesign toolbar.

- ```

## Software Implementation

The software design example performs the following operations:

- Initializing and configuring the MMUART\_0 with 115200 baud rate, 8 data bits, 1 stop bit, no parity, and no flow control. This is done by adding MICROSEMI\_STUDIO\_THRU\_MMUART0 symbol in the project settings as shown in Figure 35.

Figure 35 • MICROSEMI\_STUDIO\_THRU\_MMUART0 Symbol Settings

- Initializing and configuring the GPIOs (MSS\_GPIO\_0 to MSS\_GPIO\_7 are configured in the output mode).
- Initializing the DDR3 SDRAM:
  - 16777216x4 locations, starting from address 0xA0000000, are filled with zeros.
  - 8x1024x4 locations, starting from address 0xA1000000, are filled with incremental patterns.
- Initializing the eSRAM: 8x4 locations, starting from address 0x20008104, are filled with zeros.
- Performing the data integrity checks.
- Sending a command to AXI master for reading operation through GPIOs.
- Sending a command to AXI master for writing operation through GPIOs.

List of firmware drivers used in this application:

- SmartFusion2 MSS GPIO driver

- SmartFusion2 MSS MMUART driver: to communicate with the serial terminal program running on the host PC

In this design example, the application software performs the following steps:

1. Performing the following data integrity checks:
  - a. The Cortex-M3 processor initializes the 8x1024x4 (8 repetitions x 1024 locations x 4 bytes) locations of DDR3 SDRAM, starting from address 0xA1000000, with incremental patterns. The pattern increments from 0 to 1023, and is repeated eight times.
  - b. AXI master reads 4 KB of data from DDR3 SDRAM, starting from the address 0x01000000, that is, 0xA1000000<sup>1</sup>, and writes into LSRAM. The read operation is repeated eight times. The last 4 KB of data is fetched from the address 0x01007000, that is, 0xA1007000<sup>1</sup>.
  - c. AXI master reads 4 KB of data from LSRAM (512x64) and writes into DDR3 SDRAM, starting from address 0x00000000, that is, 0xA0000000<sup>1</sup>. The write operation is repeated eight times. The last 4 KB of data is written at the address 0x00007000, that is, 0xA0007000.
  - d. The Cortex-M3 processor compares the 4 KB data at address 0xA0007000 and 0xA1007000. The status is printed on HyperTerminal with error count, if any.

**Note:** The address map to access the DDR memory from MSS masters through MDDR is 0xA0000000-0xDFFFFFFF.

2. Initializing the DDR3 SDRAM again.
3. Perform the read operation. Uncomment any of the following lines based on the size of data to be read from DDR3 SDRAM. The default size is 2 KB.

```
/* DDR3 SDRAM READ OPERATION
 * Performing the read operation. Uncomment the any of the following lines
 * based on the size of the data to be read from DDR3 SDRAM. The default size is 2KB*/

//MSS_GPIO_set_outputs(0x26); // 2KB
//delay(50); // 2KB
//MSS_GPIO_set_outputs(0x24); // 2KB

//MSS_GPIO_set_outputs(0x4A); // 4KB
//delay(50); // 4KB
//MSS_GPIO_set_outputs(0x48); // 4KB

//MSS_GPIO_set_outputs(0x6E); // 8KB
//delay(50); // 8KB
//MSS_GPIO_set_outputs(0x6C); // 8KB

//MSS_GPIO_set_outputs(0x92); // 16KB
//delay(50); // 16KB
//MSS_GPIO_set_outputs(0x90); // 16KB
```

4. Printing the read throughput values on HyperTerminal.
5. Performing the write operation. Uncomment any of the following lines based on the size of data to be written into DDR3 SDRAM. The default size is 2 KB.

```
/* DDR3 SDRAM WRITE OPERATION
 * Performing the write operation. Uncomment the any of the following lines based on
 * the size of the data to be written into DDR3 SDRAM. The default size is 2KB */

//MSS_GPIO_set_outputs(0x25); // 2KB
//delay(50); // 2KB
//MSS_GPIO_set_outputs(0x24); // 2KB

//MSS_GPIO_set_outputs(0x49); // 4KB
//delay(50); // 4KB
//MSS_GPIO_set_outputs(0x48); // 4KB

//MSS_GPIO_set_outputs(0x6D); // 8KB
//delay(50); // 8KB
//MSS_GPIO_set_outputs(0x6C); // 8KB

//MSS_GPIO_set_outputs(0x91); // 16KB
//delay(50); // 16KB
//MSS_GPIO_set_outputs(0x90); // 16KB
```

6. Printing the write throughput values on HyperTerminal.

## Running the Design

The design example is designed to run on the SmartFusion2 Advanced Development Kit board. For more information about the kit board, refer to <http://www.microsemi.com/products/fpga-soc/design-resources/dev-kits/smartfusion2/smartfusion2-advanced-development-kit>.

### Board Jumper Settings

Table 5 lists the jumpers that need to be connected on SmartFusion2 Advanced Development Kit board.

**Table 5 • SmartFusion2 Advanced Development Kit Jumper Settings**

| Jumper                | Pin (From) | Pin (To) | Comments                                                                                                                    |
|-----------------------|------------|----------|-----------------------------------------------------------------------------------------------------------------------------|
| J116, J353, J354, J54 | 1          | 2        | These are the default jumper settings of the Advanced Development Kit Board. Ensure that these jumpers are set accordingly. |
| J123                  | 2          | 3        |                                                                                                                             |
| J124, J121, J32       | 1          | 2        | JTAG programming via FTDI                                                                                                   |

**Note:** Switch OFF the power switch, **SW7**, while connecting the jumpers.

### Host PC to Board Connections

1. Connect the FlashPro4 programmer to the FP4 HEADER J37 connector of the SmartFusion2 Advanced Development Kit board.
2. Connect the J33 connector on the SmartFusion2 Advanced Development Kit board to the host PC using the USB mini-B (FTDI interface) cable.

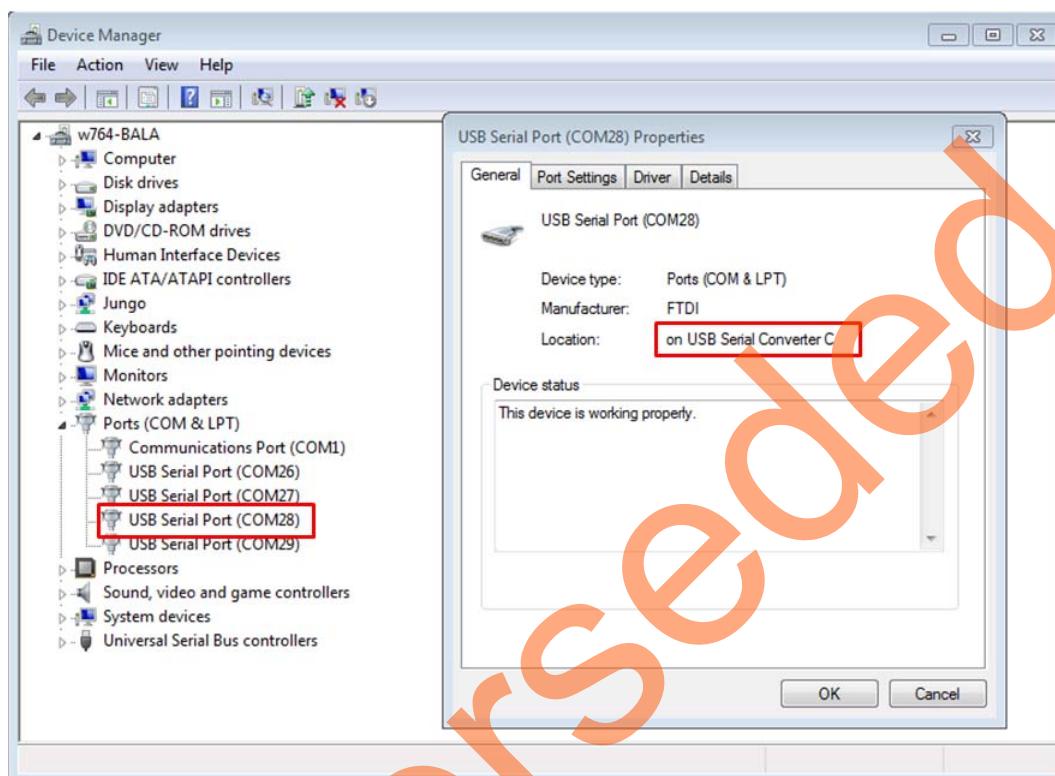

### USB Driver Installation

Install the FTDI D2XX driver for serial terminal communication through the FTDI mini USB cable. The drivers and installation guide can be downloaded from [www.microsemi.com/soc/documents/CDM\\_2.08.24\\_WHQL\\_Certified.zip](http://www.microsemi.com/soc/documents/CDM_2.08.24_WHQL_Certified.zip).

Ensure that the USB to UART bridge drivers are detected by verifying the Device Manager, as shown in Figure 36 on page 31.

**Note:** Copy the COM port number for serial port configuration. Ensure that the COM port **Location** is specified as **on USB Serial Converter C**, as shown in Figure 36.

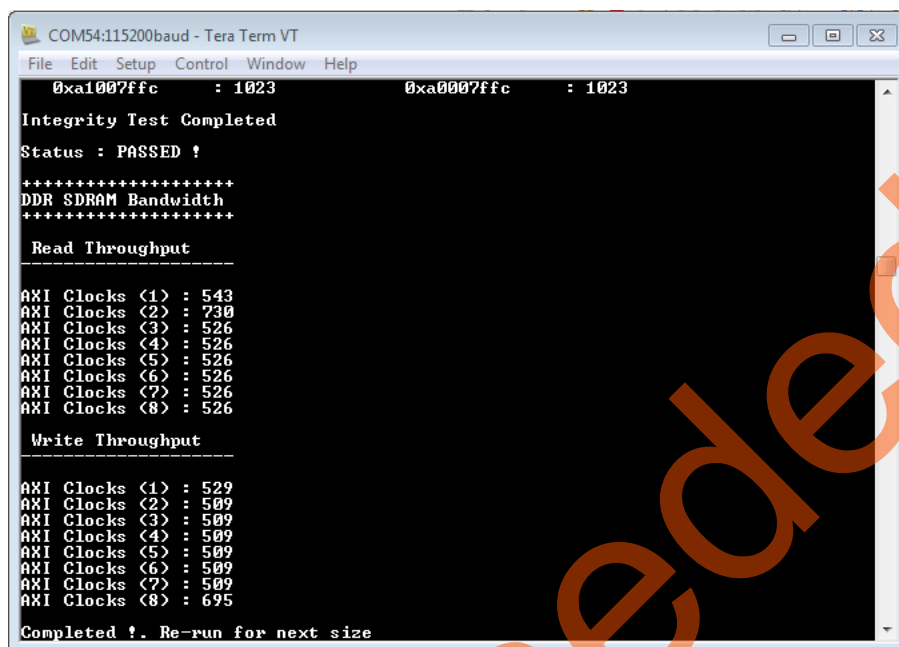

**Figure 36 • USB to UART Bridge Drivers**

## Steps to Run the Design

1. Connect the power supply to the J42 connector and FlashPro programmer.
2. Switch **ON** the power supply switch, **SW7**.
3. Program the SmartFusion2 Advanced Development Kit board with the generated or provided \*.stp file (Refer to "[Appendix: Design Files](#)" on page 37) using FlashPro.
4. Invoke the SoftConsole3.4 integrated design environment (IDE) and launch the debugger.
5. Start the HyperTerminal program with the baud rate set to 115200, 8 data bits, 1 stop bit, no parity, and no flow control. If the PC does not have HyperTerminal, use any free serial terminal emulation program, such as PuTTY or TeraTerm. Refer to the [Configuring Serial Terminal Emulation Programs Tutorial](#), for configuring HyperTerminal, TeraTerm, and PuTTY.

When the debugger runs in SoftConsole, the HyperTerminal window is displayed with the data integrity check-status followed by the read and write throughputs. [Figure 37](#) shows the total number of AXI clocks used for 2 KB of data transferred from LSRAM to DDR3 SDRAM and DDR3 SDRAM to LSRAM.

**Figure 40 • Throughput for 16 KB Data**

## DDR3 SDRAM Bandwidth

Table 6 provides the total number of 16-beat bursts corresponding to the write or read size.

**Table 6 • Total Number of 16 Beat Bursts**

| Write or Read Data Size | Total Number of 16 Beat Bursts |
|-------------------------|--------------------------------|
| 2 KB                    | 16                             |
| 4 KB                    | 32                             |
| 8 KB                    | 64                             |
| 16 KB                   | 128                            |

The following equation is applied to calculate the throughput:

$$\text{Bandwidth (MB/s)} = (16 \div (\text{Total number of AXI clocks} \div \text{Total number of 16 beat bursts})) \times 8 \times \text{AXI clock (MHz)}$$

EQ 1

## Simulation Result

Table 7 lists the write and read bandwidths of DDR3 SDRAM simulation. The incremental pattern of size varies from 2 KB to 16 KB, which is transferred from LSRAM to DDR3 SDRAM and DDR3 SDRAM to LSRAM.

**Table 7 • DDR3 SDRAM Bandwidth - Simulation Result**

| SI No | Optimization Techniques                                                                    | Size  | Write            |                    | Read             |                    | Write Improvement  | Read Improvement  |

## Board Test Result

Table 8 lists the write and read bandwidth of DDR3 SDRAM on SmartFusion2 Advanced Development Kit board. The incremental pattern of size varies from 2 KB to 16 KB, which is transferred from LSRAM to DDR3 SDRAM and DDR3 SDRAM to LSRAM.

**Table 8 • DDR3 SDRAM Bandwidth - Board Test Result**

| SI No | Optimization Techniques                                                                      | Size | Write            |                    | Read             |                    | Write Improvement  | Read Improvement  |

## Conclusion

This application note describes the DDR SDRAM bandwidth optimization techniques with an example design on the SmartFusion2 Advanced Development Kit board. It also shows the DDR SDRAM simulation flow using the Micron DDR3 SDRAM model and the Microsemi DDR3 SDRAM VIP model.

## Appendix: Design Files

The design files can be downloaded from the Microsemi website:

[http://soc.microsemi.com/download/rsc/?f=m2s\\_ac422\\_liberov11p6\\_df](http://soc.microsemi.com/download/rsc/?f=m2s_ac422_liberov11p6_df)

The design file consists Libero SoC Verilog project, SoftConsole software project, MDDR Configuration files, Simulation model files, and programming files (\*.stp) for the SmartFusion2 Advanced Development Kit board. Refer to the `Readme.txt` file included in the design file for the directory structure and description.

Microsemi Corporation (Nasdaq: MSCC) offers a comprehensive portfolio of semiconductor and system solutions for communications, defense & security, aerospace and industrial markets. Products include high-performance and radiation-hardened analog mixed-signal integrated circuits, FPGAs, SoCs and ASICs; power management products; timing and synchronization devices and precise time solutions, setting the world's standard for time; voice processing devices; RF solutions; discrete components; security technologies and scalable anti-tamper products; Ethernet Solutions; Power-over-Ethernet ICs and midspans; as well as custom design capabilities and services. Microsemi is headquartered in Aliso Viejo, Calif., and has approximately 3,600 employees globally. Learn more at [www.microsemi.com](http://www.microsemi.com).
