## II. Total Ionizing Dose (TID) Testing

This testing is designed on the base of an extensive database (see TID data of antifuse-based FPGAs at <http://www.klabs.org> and <http://www.microsemi.com/soc>) accumulated from the TID testing of many generations of antifuse-based FPGAs.

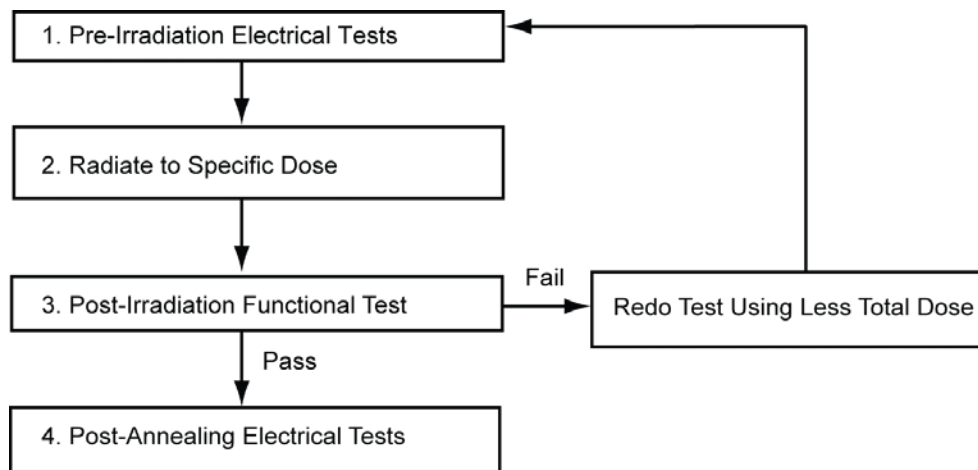

### A. Device-Under-Test (DUT) and Irradiation Parameters

Table 1 lists the DUT and irradiation parameters. During irradiation, each input and most of the output is grounded through a 1 M $\Omega$  resistor; during annealing, each input or output is tied to the ground or VCCI with a 2.7 k $\Omega$  resistor. Appendix A contains the schematics of the irradiation-bias circuit.

## B. Test Method

**Figure 1 Parametric Test Flow Chart**

The test method generally follows the guidelines in the military standard TM1019.8. Figure 1 is the flow chart describing the steps for functional and parametric tests, irradiation, and post-irradiation annealing.

The accelerated aging, or rebound test mentioned in TM1019.8, is unnecessary; because there is no adverse time-dependent effect (TDE) in Microsemi products manufactured by deep sub-micron CMOS technologies. Elevated temperature annealing basically reduces the effects originating from radiation-induced leakage currents. As indicated by test data in the following sections, the predominant radiation effects in RTAX2000S are due to radiation-induced leakage currents.

Room temperature annealing is performed in this test; the duration is approximately 7 days.

## C. Design and Parametric Measurements

The DUT uses a high utilization, generic design (TOP\_AX2000S\_TID) to evaluate total dose effects for typical space applications. Appendix B contains the schematics and Verilog files of this design.

Table 2 lists measured electrical parameters and the corresponding logic design. The functionality is measured on the output pin (O\_BS) of a combinational buffer-string with 14,000 buffers, output pins (O\_ANDP\_CLKF, O\_ORP\_CLKF, O\_FF\_CLKF, O\_ANDC\_CLKF, O\_ORC\_CLKF, O\_ANDP\_CLKG, O\_ORP\_CLKG, O\_FF\_CLKG, O\_ANDC\_CLKG, O\_ORC\_CLKG, O\_ANDP\_CLKH, O\_ORP\_CLKH, O\_FF\_CLKH, O\_ANDC\_CLKH, O\_ORC\_CLKH, O\_ANDP\_HCLKA, O\_ORP\_HCLKA, O\_FF\_HCLKA, O\_ANDC\_HCLKA, and O\_ORC\_HCLKA) of four (4) shift registers with 10,728 bits total, and half of the output pins (OUTX0, OUTX1, OUTX2, OUTX3, OUTX4, OUTX5, OUTX6 and OUTX7) of the embedded RAM configured as 16K×16.

ICC is measured on the power supply of the logic-array (ICCA) and I/O (ICCI) respectively. The input logic threshold (VIL/VIH) is measured on single-ended inputs EN8, DA, IO\_I1, IO\_I2, IO\_I3, IO\_I4, IO\_I5 and IO\_I6, and also on differential inputs DIO\_I1P, DIO\_I2P, DIO\_I3P, DIO\_I4P, DIO\_I5P, DIO\_I6P and DIO\_I7P. The differential inputs are configured as LVPECL instead of LVDS; because LVPECL using 3.3 VDC, is worse than LVDS which uses 2.5 VDC. During the measurement on the differential inputs, the N (negative) side of the differential pair is biased at 1.8 V. The output-drive voltage (VOL/VOH) is measured on QA0 and YQ0. The propagation delay is measured on the output (O\_BS) of the buffer string; the definition is the time delay from the triggering edge at the CLOCK input to the switching edge at the output O\_BS. Both the delays of low-to-high and high-to-low output transitions are measured; the reported delay is the average of these two measurements. The transition characteristics, measured on the output O\_BS, are shown as oscilloscope captures.

### III. Test Results

#### A. Functionality

Every DUT passed the pre-irradiation and post-annealing functional tests. The as-irradiated DUT is functionally tested on the output (O\_FF\_HCLKA) of the largest shift register.

#### B. Power Supply Current (ICCA and ICCI)

Figure 2 through Figure 7 plot the influx standby ICCA and ICCI versus total dose for each DUT. The post-annealing ICC for four different bit patterns, all '0', all '1', checkerboard and inverted-checkerboard, in the RAM are basically the same.

In compliance with TM1019.8 subsection 3.11.2.c, the post-irradiation-parametric limit (PIPL) for the post-annealing ICCI in this test is defined as the addition of highest ICCI, ICCDA and ICCDIFFA values in Table 2-4 of the *RTAX-S/SL and RTAX-DSP Radiation-Tolerant FPGAs* datasheet:

[http://www.microsemi.com/soc/documents/RTAXS\\_DS.pdf](http://www.microsemi.com/soc/documents/RTAXS_DS.pdf)

For ICCA, the PIPL is 500 mA; the PIPL of ICCI equals to  $35 + 10 + 3.13 \times 7 = 66.91$  (mA). Note that there are 7 pairs of differential LVPECL inputs in each DUT.

Table 3 summarizes the pre-irradiation, post-irradiation right after irradiation and before anneal, and post-annealing ICCA and ICCI data.

**Table 3 Pre-Irradiation, Post Irradiation and Post-Annealing ICC**

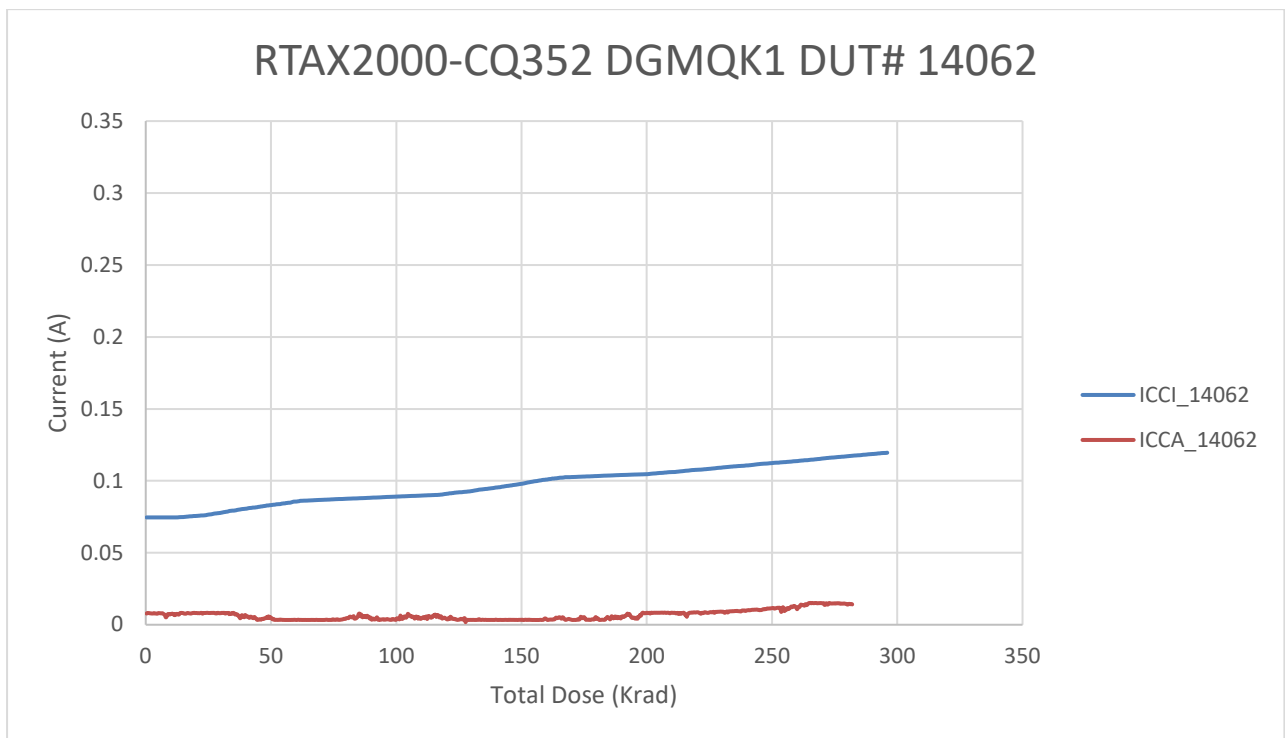

DUT	Total Dose	ICCA (mA)			ICCI (mA)		
		Pre-irrad	Post-irrad	Post-ann	Pre-irrad	Post-irrad	Post-ann
14035	100 krad	4.5	4.3	4.1	26.8	28.5	27.6
14045	100 krad	3	3.1	2.9	27.6	29.5	28.3
14049	200 krad	5.8	6.5	5.5	27.7	59.3	38
14062	200 krad	6	9.2	7	55	81.7	57
14063	300 krad	3.3	64.4	7.5	28	141	59.3
14064	300 krad	2.6	83.5	9.5	26.8	138	56.8

Based on these PIPL, post-annealed DUT passes both the ICCA and ICCI spec for 300 krad (SiO2).

## F. Propagation Delay

The propagation delay was measured in-situ, post-irradiation, and post-annealing. The results are plotted in Figure 8, and listed in Table 8. As shown in Figure 8, the propagation delay moves with the total dose, but the change is small throughout the irradiation. Referring to influx static current plots (Figure 2 through Figure 7), a device probably heats up as the dose increases. The rising temperature could be the root cause of the increasing trend at high doses. The post-annealing data, on the other hand, show decreased delay in every case.

The radiation delta in every case is well within the 10% degradation criterion. The user can take the worst case for the design margin consideration.
